

BOOKS ON
NATURAL HISTORY, BOTANY, &c.

1.
M'INTOSH and KEMP'S BRITISH YEAR-BOOK
for the COUNTRY for 1856: An Annual of Agriculture, Horticulture, Floriculture, and Arboriculture. Fcp. 8vo. 4s. 6d.

2.
WILSON'S BRYOLOGIA BRITANNICA: Being
a New Edition of *Hooker and Taylor's British Mosses*; with 61 Plates. 8vo. price 42s.; with coloured Plates, £4. 4s.

3.
HOOKER and ARNOTT'S BRITISH FLORA;
comprising the Phanogamous or Flowering Plants and the Ferns. *The Seventh Edition, enlarged*; with 12 Plates. 12mo. price 14s.; with coloured Plates, 21s.

4.
Dr. LINDLEY'S INTRODUCTION to BOTANY.
New Edition, with Corrections and copious Additions; 6 Plates and numerous Woodcuts. 2 vols. 8vo. price 24s.

5.
Dr. LINDLEY'S THEORY and PRACTICE of
HORTICULTURE: An Attempt to Explain the chief Operations of Gardening upon Physiological Principles. *Second Edition, greatly enlarged*; with 98 Woodcuts. 8vo. price 21s.

6.
LOUDON'S ENCYCLOPÆDIA of GARDENING;
comprising Horticulture, Floriculture, Arboriculture, and Landscape Gardening. *New Edition*; with numerous Woodcuts. 8vo. price 50s.

7.
LOUDON'S ENCYCLOPÆDIA of PLANTS, in-
cluding all now found in or which have been introduced into Great Britain. *New Edition, corrected to 1855* by Mrs. LOUDON; G. DON, F.L.S.; and D. WOOSTER. 8vo. with 12,000 Woodcuts, 73s. 6d.

8.
LOUDON'S ENCYCLOPÆDIA of TREES and
SHRUBS; being the *Arboretum et Fruticetum Britannicum* abridged; with 2,000 Woodcuts. 8vo. price 50s.

9.
CATLOW'S POPULAR CONCHIOLOGY; or, the
Shell Cabinet arranged according to the Modern System. *Second Edition, much improved*; with 405 Woodcut Illustrations. Post 8vo. price 14s.

10.
VAN DER HOEVEN'S HANDBOOK of ZOOLOGY.
Translated from the *Second Dutch Edition* (with *Additions* supplied by the Authors by the Rev. W. CLARK, M.D., F.R.S. Vol. I. *Invertebrate Animals*; with numerous Illustrations. 8vo.

11.
TODD'S CYCLOPÆDIA of ANATOMY and
PHYSIOLOGY. 8vo. with numerous Engravings on Wood. Vol. I. price 40s.; Vols. II. and III. 50s. each; Vol. IV. 70s.; Vol. V., completing the work, is *in the press*.

12.
Mrs. LEE'S ELEMENTS of NATURAL HISTORY;
or, First Principles of Zoology: With amusing and instructive Anecdotes of Animals, and Woodcuts. Fcp. 8vo. price 7s. 6d.

13.
The STEPPING-STONE to NATURAL HISTORY:
Vertebrate or Back-boned Animals, viz. *Mammalia, Birds, Reptiles, and Fishes*. By JAMES OWEN. With 66 Wood Engravings. 18mo. price 2s. 6d.

14.
MAUNDER'S TREASURY of NATURAL HIS-
TORY, or POPULAR DICTIONARY of ANIMATED NATURE. *New Edition, revised*, with 500 Woodcuts. Fcp. 8vo. price 10s.

15.
The FOOD of LONDON: A Sketch of its chief
Varieties, Sources of Supply, probable Quantities, Modes of Arrival, Processes of Manufacture, suspected Adulteration, and Machinery of Distribution. By GEORGE DONN. Post 8vo. 10s. 6d.

LONDON: LONGMAN, BROWN, GREEN, LONGMANS, and ROBERTS

A
DICTIONARY
OF
PRACTICAL MEDICINE:

COMPRISING
GENERAL PATHOLOGY,
THE NATURE AND TREATMENT OF DISEASES,
MORBID STRUCTURES,
AND THE DISORDERS ESPECIALLY INCIDENTAL TO CLIMATES, TO THE SEX,
AND TO THE DIFFERENT EPOCHS OF LIFE;

WITH

Numerous Prescriptions for the Medicines recommended,

A CLASSIFICATION OF DISEASES ACCORDING TO PATHOLOGICAL PRINCIPLES,

A COPIOUS BIBLIOGRAPHY, WITH REFERENCES;

AND

AN APPENDIX OF APPROVED FORMULÆ:

THE WHOLE FORMING A LIBRARY OF PATHOLOGY AND PRACTICAL MEDICINE, AND A
DIGEST OF MEDICAL LITERATURE.

BY

JAMES COPLAND, M.D. F.R.S.

FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS;

CONSULTING PHYSICIAN TO QUEEN CHARLOTTE'S LYING-IN HOSPITAL;

CONSULTING, AND LATE SENIOR, PHYSICIAN TO THE ROYAL INFIRMARY FOR DISEASES
OF CHILDREN;

FORMERLY SENIOR PHYSICIAN TO THE SOUTH LONDON DISPENSARY;

FELLOW OF THE ROYAL MEDICAL AND CHIRURGICAL SOCIETIES OF LONDON AND BERLIN,
AND OF THE ROYAL ACADEMY OF MEDICINE OF BELGIUM, ETC.

Pillsbury Academy of Medicine,

PRINTED BY RICHARD CLAY AND COMPANY, BUNGAY, SUFFOLK.
SOLD BY ALL BOOKSELLERS.
IN THREE VOLUMES.

20, 27, 23

VOL. I.

LONDON:

LONGMAN, BROWN, GREEN, AND LONGMANS,
PATERNOSTER-ROW.

1844.

*LIBRARY OF THE
Pillsbury Academy of Medicine,
NOT TO BE REMOVED*

DICTIONARY

OF

PRACTICAL MEDICINE.

ABDOMEN. SYN. *Ventre*, Fr. *Unterleib*, *Bauch*, Ger. *Ventre*, *Pancia*, Ital. *Belly*, Eng. EXTERNAL EXAMINATION OF THE ABDOMEN IN DISEASE.

CLASSIFICATION.—PATHOLOGY. *Semeiology*, or *Symptomatology*; *Diagnosis*.

1. The abdomen may be considered as the fundamental part of the frame, inasmuch as it is never wanting in monstrous fetuses; and as it contains parts which are the first formed in the embryo, and are the centres and sources of organic life. The number and importance of the viscera contained in its cavity; the number, the diversity, the extreme frequency and complication, of the maladies to which these viscera are liable, are circumstances which pressingly urge upon the practitioner a careful examination of the parietes of this cavity, in order to ascertain the nature and extent of disease. Much, however, will depend upon the manner in which the examination is made, in respect both of acquiring information as to the existing state of disease, and of drawing inferences as to its origin, and the best means of removing it.

2. Pathologists have generally divided the abdomen into certain *Regions*, with the view of describing with more accuracy the seat of morbid actions. These regions are marked out by means of imaginary lines, drawn in horizontal and vertical directions. The horizontal lines, four in number, divide this cavity into three zones. The highest of these lines passes over the xiphoid cartilage; the second, by the margin of the tenth rib; the third, by the anterior and superior spine of the ilia; and the fourth, by the superior margin of the pubis; thus giving three zones, the epigastric, the umbilical, and the hypogastric.

3. For the sake of additional precision, each of these zones is divided into segments by vertical lines, also four in number, drawn from the acromial extremity of the right and left clavicles to the insertion of the ligaments of Poupart; and from the posterior margins of the axillæ, over the most exterior part of the crests of the ilia, to the large trochanters. The spinous processes of the vertebræ may likewise be considered as forming a fifth line of demarcation; as we cannot overlook the posterior parts of the body in our investigation of many of the diseases affecting the abdominal organs. The vertical lines now enumerated, dividing the horizontal lines very nearly at right angles, give us nine regions on the anterior and lateral aspects of the abdomen, and six posterior regions. The *anterior* regions are the epigastric, umbilical, hypogastric, and right and left inguinal;

the *lateral* regions are the right and left hypochondriac and right and left iliac; the *dorsal* regions are inferior dorsal—right and left, the right and left lumbar, and the right and left gluteal regions.

4. It does not belong to the scope of this work to enumerate the anatomical boundaries of the abdomen; the parts forming its parietes; or the viscera contained in each region. These are matters which are, or ought to be, familiar to all who peruse this work. But it is necessary to remind the reader, that organs which, in the healthy state, are always situate in a particular region, will be so changed in form and bulk by disease as frequently to extend to adjoining regions, where they will often be detected upon a careful examination; or they will be altogether displaced, either by the specific gravity of their contents, or by tumours developed in their structure. The former phenomenon is often remarked in respect of the liver, spleen, kidneys, ovarium, uterus, &c.; the latter, in the stomach, pylorus, gall-bladder, colon, &c.

5. This change of the position of the abdominal viscera is chiefly observed in the more chronic kinds of organic diseases, and is pointed out in the articles in which they are described: it is generally more manifest in one posture of the body than in others; and is to be ascertained, with the other maladies to which these viscera are liable, by the modes of examining the abdomen about to be explained, assisted by other rational or inferential symptoms. These modes may be made the source of much information as to all the relations of abdominal diseases; but attention, repeated observations, and much natural discernment, are required to obtain from them all the knowledge they are capable of conveying. I shall discuss this subject, in the brief manner to which I am necessarily driven, by noticing—1. *Inspection*; II. *Manual examination*; III. *Percussion*; and IV. *Auscultation* of the abdomen.

6. I. **INSPECTION** by the sense of sight merely, although the best mode of acquiring an idea of the form, size, and motions of the abdomen, is chiefly valuable as a means of investigating the diseases of its viscera in conjunction with the other modes just enumerated: yet simple inspection furnishes us with the most important information in many diseases, particularly in those of infancy and childhood, as well as in many acute and chronic maladies occurring in adults. The *form* of the abdomen, although necessarily in some measure changed by marked variation of its bulk, may, nevertheless, be much altered without any decided

difference in its size. Thus, it is somewhat changed in severe diseases of the respiratory passages, when the entrance of air into the lungs is obstructed; the epigastrium and hypochondria being then pressed inwards and upwards: whilst in some morbid states of the liver and gall-bladder, of the spleen, and of the ovaria, an unusual prominence in their respective regions is frequently observed. But the most remarkable changes in the form of the abdomen is met with when the size of the cavity is also altered. It is scarcely necessary to allude to examples; but, in all those diseases attended with enlargement or diminution of the bulk of this important part of the body, either in one of its regions, in several of them, or in all, inspection should always be performed: it gives greater precision to manual examination; enables us to compare the bulk of a region with the corresponding region on the other side, and with others in its vicinity; and impresses upon the memory the changes which the part may experience during the progress of disease. It should, therefore, never be neglected in all the forms of abdominal dropsy; in peritonitis, chronic or acute; in inflammation of the stomach, liver, spleen, and bowels; in the different kinds of colic, in fevers, in uterine and ovarian diseases; in affections of the kidneys and urinary organs; in all disorders accompanied with obstruction to the excretions; and, in short, in all chronic maladies. It ought never to be overlooked in the diseases of infancy and childhood, of whatever nature they may be.

7. Besides, however, attending in those diseases to the form and size of the abdomen merely, the *motions* which it presents ought not to be neglected. When rightly interpreted, they often furnish important diagnostic and therapeutic hints. But they require to be viewed in connection with the motions of the thorax, and state of the heart's action. In diaphragmitis, peritonitis, gastritis, enteritis, and certain states of hepatitis, the motions of the abdomen are slight or obscure, whilst the actions of the thorax are increased. On the other hand, in several severe diseases of the respiratory organs, particularly in croup, laryngitis, bronchitis, several varieties of asthma, pleuritis, pneumonia, &c., the parietes of the chest are nearly motionless; whilst the movements of the abdomen, especially at the epigastrium, in croup and asthma, are remarkably increased, or laborious. The motions of the abdomen, also, are often not limited to those caused by respiration; but in some cases, particularly in organic changes of the heart, pericardium, aorta, &c., and even in certain nervous disorders implicating these organs, comprise those occasioned by the action of the heart, increased by the state of the large abdominal vessels, and by the emaciation or other morbid conditions of the patient.

8. 11. MANUAL EXAMINATION of the abdomen is one of the most important means of diagnosis we possess: but it furnishes information in proportion to the perfection of manner in which it is made. In this very requisite mode of investigation, the temperature of the hand of the practitioner at the time of making it should be attended to, in the great majority of diseases; both as a moderate warmth of the hand is necessary to the greatest delicacy and accuracy of touch, and as its application to the surface of the abdomen will not in that state occasion any disturbance or con-

traction of the muscular parietes. In entering upon the examination, care should be taken not to excite the alarm of the patient. The hand ought to be applied at first in the gentlest manner possible. By observing this, three very important objects will be best obtained; namely, a knowledge of the form, of the temperature, and of the sensibility of the surface of the abdomen.

9. As much more information than this is required from manual examination, the patient should be directed to place himself in a favourable position for a more general and complete investigation. He should be placed on his back, with the head and shoulders slightly and comfortably elevated, and the thighs drawn nearly to a right angle with the trunk. If the bladder be full, it should be emptied. When proceeding to examine, the patient should be told to relax all the muscles, particularly the abdominal muscles. Commencing, therefore, with the utmost gentleness, and passing the hand slightly over the abdomen, we should slowly increase the pressure, with the view of ascertaining the following conditions:—1st, Its temperature; 2d, Its form and size; 3d, Its sensibility; 4th, Its degree of tension and firmness; 5th, The existence of enlargements, tumours, &c.; 6th, The presence of effused fluids; 7th, The probable existence of accumulated secretions and faecal matters; 8th, Hernial protrusions and displacements. On each of these I proceed to offer a few remarks.

10. 1st, The *temperature* of the abdomen furnishes most important indications as to the nature of disease. It is generally always higher than natural in diseases of increased action; and is also often higher when the patient is actually complaining of cold, particularly at the commencement of fevers. In many fevers and inflammations of the abdominal viscera, particularly those of a dangerous or malignant character, the increased temperature is accompanied with a peculiar acrid pungency to the sensation of the examiner; a phenomenon which indicates the utmost risk of rapidly supervening disorganisation. *Diminished temperature* of the abdomen is met with in the period of depression, or cold stage at the commencement of fevers, but very seldom at their termination, even in death, unless in the most malignant or liquescent forms. It is also met with after injuries of the abdomen, particularly blows on the epigastrium, in anæmia, chlorosis, and other disorders of debility.

11. 2d, The *form and size* of the abdomen are frequently altered, as already noticed (§ 6, 7.); but, in order to ascertain the nature of the alteration, various means of investigation are generally required, particularly those which remain to be considered. When proceeding with the manual examination of the abdomen, it is necessary very gently to increase the pressure, and, when acute pain is not complained of, to make it in various directions,—laterally, downwards, upwards, and backwards to the spine,—so that if altered sensibility of any of the contained viscera exist, it may not escape detection, but be accurately ascertained and estimated; and the examination should always be made with a careful observation of its effects upon the expression of the countenance of the patient. It will also often be requisite to perform the manual examination, now with the points of several fingers, now with the whole of one, or

even of both hands; and occasionally, at the same time that a full inspiration is being made. But it should always be performed with attention to the sensations of the patient, particularly as expressed by the countenance, and to the feelings and ideas it may excite in our own minds. Even the state of action in which the abdominal muscles are often thrown by the examination; the degree of pressure occasioning such action; and the circumstance of tension of those muscles preceding the examination, or being excited by it, as well as the continuance of their contractions, and the periods and occasions of their relaxation, are all important matters in our estimate of the state of the viscera underneath, — more particularly in the various states of inflammation seated in the peritoneum, in the alimentary canal, &c.

12. 3.) The *sensibility* of the parietes of the abdomen is most intimately associated with that of the contained organs, both in health and disease. The sensibility of the epigastric region varies most widely in different persons. It is frequently, even in tolerable health, very great in delicate and thin females. It is always so in inflammation of the viscera, more particularly when the serous membranes are affected; and the more superficial the inflammation, the more tender is the surface. In order to obtain an accurate idea of the state of the sensibility of the abdomen, pressure should be commenced in the gentlest manner, and with the fingers and palm of the open hand. When the patient cannot endure the slightest touch, the disease is then commonly in the parietes, or in the serous membrane reflected over them. When the cause exists more deeply, the tenderness is less acute, and the muscles are almost instinctively brought into action, even before pressure is made, in order to protect the diseased viscera from it.

13. When superficial tenderness is absent, the examination may be made with increased pressure, in order to ascertain the presence of tenderness, pain, or soreness, in any degree or at any part. But caution in thus increasing the pressure is always necessary when the parenchyma of an organ, particularly of the liver or spleen, is enlarged or otherwise affected; for many such affections may be very serious, and yet the sensibility of the diseased part not much increased. I have known rupture of an enlarged and softened spleen occasioned by the rudeness of the examination; and writers have mentioned similar accidents to have occurred to the liver.

14. 4th, The *tension and firmness* of the abdomen require attention, and due estimation of their actual amount; and in connection with the other diagnostic indications furnished by the examination. Thus, when the tension is associated with increased temperature and sensibility, inflammation of one or more organs underneath, particularly of the peritoneum, may be predicated. The tumefaction, degree of sensibility, position of the patient, &c. will further prove the accuracy of the diagnosis. Tension and firmness are always present in the different forms of peritonitis and inflammations of the subjacent viscera, but not uniformly throughout all their stages. Even in the worst or most malignant forms of peritonitis, as those met with in puerperal females, these symptoms are often either almost altogether wanting, or they exist for a short time only. When

effusion of a serous or sero-purulent matter occurs in peritonitis, or when suppuration has followed inflammation of the enveloped viscera, tension as well as firmness disappear. They are generally, however, both present even when the sensibility of the parietes is not much greater than natural, in chronic peritonitis with the formation of false membranes, or the agglutination of the opposing surfaces of the viscera.

15. 5th, The *presence of tumours* or other morbid growths, or the fact of their absence, has also to be ascertained by a manual examination. This information can be obtained only by this mode of investigation, carefully conducted. If we detect any degree of unusual tumefaction or hardness, we should endeavour to ascertain its exact site; its form, size, connections; its consistence, degree of sensibility; and whether it is fixed or moveable, soft and yielding, or hard; pulsatile or not. The situation of the tumour; its size, form, and degree of fixedness, will enable us to form an idea of the part affected: whilst the absence or presence of morbid sensibility in it, of fluctuation and pulsation, and the manner in which the nearest parts of the abdominal parietes are affected by it, will furnish important indications of its nature. When tumours or unusual circumscribed indurations are detected in any part of the abdomen, we should bear in mind that their sources and kinds are numerous: that they may be formed in the liver, pancreas, spleen, stomach, pylorus, mesentery, omentum, cæcum, kidneys, uterine organs, &c.; that their nature may be extremely various; and that they may consist either of accumulations of some fluid contained in a cyst, or infiltrated in the substance of an organ, or enclosed in its natural cavity, the outlet of which has been obstructed; or of a deposition of some morbid structure, the nature of which can only be known by a comparison of numerous symptoms, and the history of the disease. Care should be also taken that the accumulations of fecal matters occasionally formed in the cæcum, and in various parts of the colon, or that an unusual anterior protuberance or curvature of the inferior dorsal or lumbar vertebra, be not mistaken, as have sometimes happened, for morbid growths; and that unusually large collections of the natural secretions in their cysts, as of the bile and urine, owing to temporary obstruction to their discharge, be not treated as morbid formations of a very different kind. I have known cases in which distension of the gall-bladder, from great accumulation of the cystic bile, was mistaken for abscess of the liver; and an enormously distended urinary bladder was viewed as dropsy.

16. 6th, The *presence of fluids effused into the peritoneal sac* is best ascertained by placing the patient in the erect posture. If this cannot be done, and if he cannot even sit up, the shoulders and limbs should be placed low; and, whether in the erect or recumbent posture, the palm of one hand laid with a gentle pressure upon one side of the abdomen, whilst we tap, somewhat smartly, with the other hand, on the opposite side. The impulse occasioned by the stroke will occasion, if fluid be effused, a vibratory undulation or shock which will be felt by the other hand, and which constitutes the diagnostic symptom in diseases of the abdomen attended with effusion.

17. 7th, *Accumulation of fecal matters* in the bowels are not infrequently mistaken for tumours. These matters usually collect and harden in the cæcum, or in some part of the colon. They seldom accumulate in the small intestines, unless they consist of certain kinds of *intestinal concretions* (see the art.); which are with difficulty distinguished from tumours seated in some one of the abdominal viscera. It is indispensably requisite to examine the abdomen carefully in all cases of habitual or occasional constipation, particularly in the region of the cæcum and course of the colon; as, when conducted with an experienced tact and discrimination, these collections will generally be ascertained: and when the history of the case, and numerous contingent rational symptoms, are taken into account, little risk will be run of confounding them with morbid growths. The accumulation of secretions in the gall-bladder, and in the urinary bladder, are chiefly, particularly the latter, ascertained by manual examination. The diagnosis of those disorders is fully pointed out in another place.

18. 8th, *Protrusion* of some part of the abdominal contents, giving rise to any either of the more common kinds of *Hernie*, or of those which are unusual, should never be overlooked. Inguinal, femoral, and umbilical herniæ are so frequent, and, when either incarcerated or strangulated, occasion so serious effects, that in all cases where severe symptoms are referred to any of the viscera contained in the abdominal cavity, or in its vicinity, or when the functions of the bowels are obstructed, this source of mischief should be particularly inquired into.

19. I may observe generally, in respect of manual examination of the abdomen, that it furnishes valuable means of diagnosis in very many diseases, particularly when estimated in due connection with those derived from other sources; but I should add,—what I shall often have to prove hereafter,—that it does not always give us exactly the same kind of information that is stated in several, and even in some very recent, works. Thus it is said to be the most certain means of ascertaining the presence of enlarged mesenteric glands, and by actually feeling these glands enlarged. Now this is not the case, and I state it from an experience of many hundred cases: for there are comparatively but few instances in which these enlarged glands can be satisfactorily detected, by the most careful manual examination. But this mode of investigation furnishes certain indications of their presence of a different kind from that which writers have laid down. It may also be remarked, that a manual examination of the abdomen is generally much more successfully made in lean subjects, in females than in males, and in children than in adults; whilst in muscular men, and in fat persons, it furnishes much less information, owing to the muscularity and thickness of the abdominal parietes.

20. III. *Percussion* has been employed as a means of diagnosis in diseases of the abdomen, from a very early period of medical knowledge, but chiefly with a view of recognising tympanitic affections, or unusual accumulations of air, and dropsical effusions; and it was not until very lately that attention was directed to it as a means of investigation in a very large proportion of other diseases of the abdominal viscera. Percussion

of the abdomen, as well as of the thorax, is either *direct* or *mediate*: the former is that which was first ably insisted on by AVENBRUGGER, and brought into notice by CORVISART, chiefly in the investigation of thoracic diseases; the latter, both in its application to abdominal and thoracic affections, is the invention of M. Piorry, who has paid great attention to its perfection, and has written ably on it as a means of diagnosis.

21. *Direct* percussion consists of simply striking the parts, somewhat smartly, with the points of two or more fingers united and brought to the same plane, and attending to the sounds elicited. *Mediate* percussion is performing the same with a thin plate of ivory, box wood, or any other hard elastic body, placed over the part to be thus examined, and striking upon it. The advantages derived from having such a body interposed between the surface and the fingers are, 1st, The part is protected in a great measure from the stroke, which, although slight, yet is frequently unpleasant to delicate and sensitive persons; 2d, It assists in the production of the sound for the obtaining which percussion is employed. (See art. *PERCUSSION*.) The body on which the percussion is thus made usually consists of a small ivory plate of about $2\frac{1}{2}$ or 3 inches in diameter; M. Piorry calls it the *pleximeter*, or measure of percussion. In all cases in which we wish to examine the abdomen by percussion, it will be necessary to use the pleximeter. The information it conveys varies according to the state of the parts underneath. If we place it over the liver, percussion gives out a dull sound; from the circumstance of a dense body lying beneath that part of the abdominal parietes: if it be moved in the course of the stomach and colon, a sound will be elicited clear in proportion to the quantity of air contained in these viscera.

22. During our investigation of the abdominal contents with the aid of mediate percussion, it will be necessary to attend to certain facts:—1st, That the pleximeter will furnish, in the same person, a sound varying from dull to tympanitic as the parts over which it may be placed differ in density and the quantity of air they may enclose; 2d, That in situations of the abdomen where, owing to the quantity of air usually contained in the bowels, mediate percussion generally gives a tympanitic sound when the plate is placed lightly on the surface, it will give a much duller, or even a dead sound, when pressed inwards so as to displace the air from underneath it, and to approach nearer to some solid body, or to bring the parts nearer to that condition by the pressure; 3d, That the stomach and whole tract of the intestinal canal always contain a certain quantity of air or gaseous fluid, particularly the large bowels; and that they approach more nearly to the abdominal parietes in proportion to their distension, whether with air, or with fluid, or more or less solid contents; and, 4th, The quantity of air contained in the digestive tube, especially the stomach and large bowels, is great in proportion to the deficiency of its vital energy, and the degree of inflammatory action affecting it.

23. These facts being attended to in our investigations of abdominal diseases by means of percussion, mediate or direct, the extent of the liver may be distinctly traced by its means; and the degree of inflation of the bowels, or stomach,

may be ascertained with tolerable certainty. When the stomach is nearly empty (for it always contains some air secreted from its internal surface), it retracts backwards, and recedes from the abdominal parietes towards the centre of the trunk; having then the colon, more or less distended with gas, placed before it. As it becomes filled with air or the ordinary ingesta, it extends to the left hypochondrium, and approaches the left and anterior parietes of the upper zone of the abdomen. In proportion to the quantity of air it contains, percussion gives out a clear sound, which is dull or dead as it is filled with fluid or solid ingesta, and as the air is displaced. When we know that the stomach must be empty of food, and yet find that a dull sound is emitted, on percussion, we should always suspect organic disease. In these cases air is often secreted with great rapidity from its internal surface, but is immediately expelled, owing to the irritable state of its muscular coats, without being retained, and before any very material distension of the viscus is occasioned by it.

24. The small intestines generally contain air; although, I believe, much less than is usually found in the large bowels. In a state of health, particularly a few hours after a meal, when the chymous matter is passing along them, percussion over them,—that is, over the umbilical region, and the immediately adjoining parts of the surrounding regions,—generally yields a dull sound; which becomes clear in proportion to the quantity of air they contain, excepting in very fat persons. In a great majority of abdominal diseases, the quantity of air contained in the small intestine is increased much beyond what exists in health: this is particularly the case in several diseases of debility, as chlorosis, indigestions, colicky affections, torpid states of the liver, constipation, certain states of fever, hysteria, &c.; and still more so in inflammatory states of portions of the digestive tube, in peritonitis, in puerperal fevers, &c.

25. When the mucous surface of the bowels or of the stomach is irritated or inflamed, the quantity of air secreted is often very great; but, excepting in the slighter states of such diseases, it is seldom retained within the sphere of the inflammation so as to occasion that degree of distension which may be detected by percussion, although it is often retained in adjoining parts of the tube, occasioning distension, great pain, tormina, &c. This disposition to expel the morbid collection of air arises from the irritability of the muscular fibres of that part of the intestines, the mucous surface of which is in a state of irritation; the morbid action of these fibres propelling it either upwards or downwards, where it may accumulate or be evacuated, but most commonly into the large bowels, or into the duodenum and stomach, where it may be detected by percussion. In diseases which paralyse the contractile actions of the muscular coats of the bowels, as malignant puerperal peritonitis, the last stages of enteritis, rabies canina, and the advanced states of adynamic fevers, the quantity of air which is secreted and accumulated in the whole digestive tube, and the consequent distension, are often enormous. The sound on percussion, in these cases, generally becomes quite tympanitic long before death, indicating the cause, as well as the lost tone of the muscular coat of the canal.

26. The phenomena now noticed to occur in

respect of the small intestines affect, in a still more marked manner, the large bowels; flatulent distension of these being readily traced by mediate, or even direct percussion, particularly in the course of the colon, even when the small intestines are comparatively free from it.

27. It is not merely the presence of accumulated air in the different parts of the digestive tube, and the important pathological and therapeutic indications to which the knowledge of this fact naturally leads, that render percussion of the abdomen a valuable means of investigation, but it is also the information it conveys of the existence of more solid formations—of fluid collections, and morbid productions. Unusual distension of the bladder; all the forms of abdominal dropsy; ovarian diseases; purulent collections in, or enlargements of, the liver; tumours of every kind, particularly when they reach a considerable size; enlargements of the spleen or kidneys, &c.; are more readily and earlier detected by means of mediate percussion than without this aid; and, in all these, the sound emitted is dead over the diseased part, and becomes clear as the boundary of disease is passed, and when the plate is placed over the hollow viscera.

28. IV. AUSCULTATION, mediate or direct, particularly the former, is often necessary in abdominal diseases, particularly in ascertaining whether or not the large vessels are affected; and even in tracing disease of the right side of the heart and of the pericardium. It may also be useful in those diseases of the liver which extend to the lungs through the diaphragm, particularly abscess, or hydatidic cysts of the liver breaking into the lungs. Auscultation of the abdomen has been resorted to by M. KERGARADE to ascertain the existence of pregnancy; and by M. LISFRANC, to determine the presence of stone in the bladder, when the sound is imperfectly heard to strike against it.

ABORTION. SYN. *Abortus*, *Aborsus*, *Affluxio*. *Διαφθορά*, *Εκτρώμα*, *Εκτρώσις*, *Αριστ.* *Αμ-ελομα*, *Εξαμβλωσις*, *Πιρ.* *Avortement*, *Fr.* *Aborto*, *Ital.* *Falche Geburt*, *Fehlgeburt*, *Ger.* *Miscarriage*, *Eng.*

CLASSIF. — 5. *Class.* Diseases of the Sexual Function; 3. *Order.* Affecting Impregnation (*Good*). I. *CLASS*; V. *ORDER* (*Author*, see *Preface*).

1. *DEFIN.* *The expulsion of an embryo or fetus which is either already dead, or is at a too early period of fetal existence to live.*

2. This definition will distinguish *abortion* from *premature labour*, which latter is applicable to delivery after the sixth month, when the fetus may live; and from *false delivery*, which signifies the expulsion of a mole, or false germ, instead of an embryo. Under this term I also include expulsion of the ovum before the sixth week, commonly called *miscarriage*.

3. I. *CAUSES.*—These may be divided into such as act primarily upon the mother, or depend upon her; and into those which are connected with the product of conception, and are owing to diseases of the fetus and its appendages.

(DUGES.) Or they may be divided into the predisposing, exciting, and efficient causes. It will be necessary to consider the causes with some relation to these distinctions.

4. *i. Predisposing causes.*—The disposition to abortion is, in some females, so strong that the slightest exciting cause will produce it; in other females the most serious injuries, and the most violent mental and moral impressions, are insufficient to occasion it. Some of the predisposing causes are referable to the mother, others to the fœtus and its appendages.

5. *A.* The predisposing causes referable to the mother are numerous, and consist of certain states of the uterus, and particular conditions of the habit and constitution, influencing either the uterus or the embryo itself.

6. The conditions of the uterus favouring abortion are great rigidity of its fibres, and an unyielding state of its parietes, opposing too great a resistance to the dilatation which the organ must necessarily experience; too great sensibility and contractility of the uterus, in the former of which states the other organs of generation often also participate; too great a flow of blood to the uterus and ovaria, either proceeding constitutionally, or from causes which excite the nerves of these organs or parts adjoining; feebleness and relaxation of the neck of the uterus — a condition of the parts which M. DESORMEAUX states he has frequently ascertained to exist in females subject to abortion; and atony of the uterus itself, either from original constitution or long-continued leucorrhœa, or from a severe or protracted labour, a cause which may be conjoined with the one preceding it. The foregoing causes are chiefly productive of those abortions which occur at the same period of pregnancy, and which have been called periodic by some authors.

7. To the above may be added, as strictly referable, a condition of the organ called by PÉU immoderate heat of the uterus, which is attributable to an excited condition of the nerves of the organ, and a chronic inflammatory or irritative state of its vessels; also scirrhous, fibrous, fleshy, steatomatous tumours of the uterus; polypus, dropsy, the presence of several children, and the too rapid or too great dilatation of the organ thereby occasioned; tumours of, and fluid effusions into, the substance of the ovaria; and inflammation of the ovaria and parts adjoining.

8. The causes chiefly referable to the constitution and habit of the mother are certain states of the atmosphere, to which only can be attributed those frequent abortions sometimes observed, which have even assumed an epidemic form, and of which HIPPOCRATES, FISCHER, TESSIER, DESORMEAUX, and others, have made mention; the sanguine and irritable temperament; plethoric habit; a constitutional disposition to hæmorrhage independently of, or connected with, the foregoing states; habitual menorrhagia; irregular menstruation; great debility of body; excessive sensibility, susceptibility, and mobility of the nervous and muscular systems; hysterical states of the nervous system; the syphilitic and the mercurial poisons; a cachectic condition of the frame; painful and chronic diseases; addiction to masturbation in early life; curvatures of the spine; malformations of the spine and pelvis; hereditary disposition; an acquired disposition arising from

previous abortions caused by accidental circumstances; marriage or impregnation late in life; deficient or improper nourishment; too close cinctures of the body; worms in the intestinal canal; conception at a too early period after delivery, or after a previous abortion; the atonic state of plethora generated by luxurious indulgences, by sleeping in soft and too warm beds, by indolence, a too full diet, &c.; local plethora, or excitement of the uterine organs, occasioned and kept up by sensual gratifications; and the constitutional and local commotion occasioned by infectious, exanthematous, pestilential, and febrile diseases.

10. *B.* The causes which depend upon the fœtus are referable either to the fœtus itself or to its appendages. They operate either by favouring the death of the fœtus, which acts then as a foreign body in the uterus, exciting the organ to expel it; or by impeding its growth, so that it does not consume, or does not afford a ready circulation to, the blood sent to the uterus; thus occasioning an accumulation of this fluid in the uterine vessels, and consequently congestion, terminating in hæmorrhage and the expulsion of the embryo. Owing to these circumstances, abortion is favoured by debility, or imperfect development of the fœtus; by monstrous conformation, and disease affecting it at some period of its early growth; by the imperfect adhesion of the placenta to the surface of the womb, or its implantation over the neck of the organ; by disease of the placenta, as inflammation, apoplectic hæmorrhage into its substance, calcareous deposits, fatty degeneration, scirrhous or cartilaginous induration; the formation of serous cysts, of hydatids, aneurism, or varices of this organ; by atrophy, hypertrophy, or disproportionate size of the placenta; by a too short or a too long umbilical cord; by twisting of the chord around the neck or one of the limbs of the fœtus; by diseased structure of the chord itself, as extreme tenacity or softness, the formation of tumours or hydatids in it, by knots or adhesions preventing or impeding the circulation through it; great tenderness of the membranes of the ovum; inflammation, thickening, opacity, and irregularity of the membranes; the presence of too much or too little amniotic fluid, and collections of serum, or of a sanguineous fluid, between the chorion and amnion; adhesions formed between the placenta and parts of the surface of the fœtus; and, in the more advanced periods of gestation, constitutional diseases, particularly eruptive and infectious diseases, or continued fevers, extending from the mother to the embryo.

10. *ii.* The occasional exciting causes are extremely numerous. It may be even said that there is scarcely an occurrence in life which may not be occasionally concerned in producing abortion. (DESORMEAUX.) The chief causes of this class are acute diseases; such as fevers, scarlatina, measles, small-pox, and inflammations, particularly of the uterus, ovaria, pelvic peritoneum, colon, &c.; the irritation of adjoining viscera; diarrhœa, dysentery, tenesmus, colic, constipation, hæmorrhoids; hysterical and epileptic convulsions; syphilis; violent pain; disappointment and anxiety of mind; anger, fright, excessive joy; the impression of various odours; threatened asphyxia, particularly from the vapour of carbon; violent exertions and fatigue; dancing; riding on

horseback, or in an uneasy carriage, or on a roughly paved road; excessive venereal indulgence; severe coughs; hiccup; immoderate laughter; vomitings; sea-sickness; injuries on the loins or abdomen; any sudden shock; even the extraction of a tooth; the use of irritating or drastic purgatives, or of emmenagogues; pediluvia; hot baths; large blood-lettings, particularly from the feet; convulsive movements of the fœtus; rupture of the umbilical cord or of the membranes; adhesions formed between the serous surface of the fundus of the uterus and the adjoining viscera, preventing the dilatation or the ascent of the womb, and occasioning its reaction on its contents.

11. The foregoing causes act variously in producing abortion. Some of them may produce directly a separation of the placenta from the surface of the uterus, particularly when the placental mass is very considerable; but this is a rare occurrence, and can only be inferred to exist when uterine hæmorrhage follows immediately upon the application of the exciting cause. A violent shock, injury, fall, compression of the uterine region, riding, dancing, coition, &c. may have the immediate effect, or they may occasion rupture of the cord or of the membranes; but more frequently these, and, in a still more particular manner, the other exciting causes, produce certain intermediate effects, as congestion of the vessels of the womb, which is soon followed by hæmorrhage and by separation of the placenta; or they occasion contractions of the uterus, owing to the excitement and irritation of its nerves, or of the nerves of adjoining or sympathising parts, the separation of the placenta, and expulsion of the fœtus.

12. KLEIN and many other authors have remarked that the causes of abortion generally have a more marked effect at the period at which the menses would have returned in the unimpregnated state. The *molimen*, or tendency to congestion in, and hæmorrhage from, the uterus, which then may be supposed to exist, renders it more susceptible of being injuriously impressed by the occasional causes of the disease; and, where other predisposing causes are already in existence, has a direct influence in separating the placenta, and inducing uterine contraction and abortion; several of the causes produce spasmodic or convulsive actions, which are sympathetically transmitted to the uterus, whilst others seem to act primarily on the fœtus. The direct action of certain of the exciting causes on the fœtus may be doubted; but every experienced and observing practitioner must have remarked the very frequent and immediate effect of strong passions of the mind of the mother upon the motions of the fœtus, inducing convulsive actions, painfully and distinctly felt, and sometimes followed by its death. Amongst the most common exciting causes of abortion are those means which, from their oseeaional action in this way, have been called *abortives*, and which the practitioner should be acquainted with, so as to enable him the better to counteract their effects.

13. The production of abortion is a felonious act, and one which the practitioner never will resort to, except in the case of irreducible retroversion of the uterus. The means usually resorted to by females themselves, or by persons

who criminally usurp the medical character, and employ feloniously the little empirical knowledge they may have acquired, either surreptitiously or otherwise, are, large bleeding from the feet; pediluvia; violent emetics; drastic purgatives, particularly those which act upon the colon and rectum; active emmenagogues, as savine, ergot of rye, juniper, hellebore, &c.; and stimulating injections into the vagina; also various mechanical means employed to break the membranes, or to procure the discharge of the amniotic fluid. Many of the foregoing, or all of them excepting the last, will often fail of producing the desired effect. They frequently also succeed, and sometimes they occasion the death of both mother and fœtus. MAURICEAU, DE LA MOTTE, BOER, DESORMEAUX, DUGES, BURNS, HAMILTON, RYAN, &c. have satisfactorily shown the uncertainty of those means, and have met with numerous instances in which they had been carried to the utmost extent without acting in the way desired; but had occasioned enteritis, dysentery, peritonitis, metritis, and other dangerous diseases. Many cases are also on record where attempts had been made to produce abortion by puncturing the membranes; and the uterus itself had been penetrated, and the death of the mother thereby occasioned. It is a matter of the utmost difficulty, even to the most expert surgeon, to puncture the membranes at that period of pregnancy when it is usually attempted by ignorant persons; the only persons, indeed, who would make he attempt.

14. II. THE SYMPTOMS of abortion vary remarkably with the period of pregnancy at which it takes place: also with the cause producing it. They do not, therefore, admit of being divided into precursory and essential symptoms: the former being frequently wanting. In the two first months of pregnancy the ovum, which is then small, is sometimes expelled without any remarkable pain or hæmorrhage; but more frequently there are pains, accompanied with coagula, in which the ovum is generally enveloped, and where it often escapes observation. This is particularly the case when, the membranes being broken, the embryo escapes without the placenta. At this early period females often suppose that they have been the subject merely of an interruption of the menses, followed by a more abundant and painful return of them than usual, instead of a true abortion or miscarriage.

15. As the period of utero-gestation advances, and the size of the fœtus increases, the pains and hæmorrhage accompanying abortion are augmented; the hæmorrhage being generally more considerable than that attending delivery at the regular period.

The abortions which proceed from chronic diseases, or from causes acting slowly, and particularly those which are occasioned by morbid states of the embryo, or of its membranes, are generally preceded by horripilations or rigors, followed by febrile movements, by heat, want of appetite, nausea, thirst, pain in the loins, lassitude, leipothymia, syncope, coldness of the extremities, palpitations, lowness of the spirits, paleness of countenance, tumefaction or lividity of the eyelids, deficient brightness of the eyes, fœtor of the breath; a feeling of weakness in the abdomen, or of cold about the pubis; of weight about the anus and vagina; flaccidity and diminished size of the

breasts, sometimes with a slight discharge of serum; a flow of a sanious, then of a sanguineous, fluid, and afterwards of blood, either in a fluid or grumous state, from the vulva; diminished motion of the child, soon afterwards followed by perfect cessation of motion; lessened bulk of the abdomen or of the hypogastrium; uterine pains, which become more and more frequent and severe; progressive dilation of the uterine orifice, and prominence of the membranes; and, lastly, expulsion of the amniotic fluid and foetus, followed, at an indefinite time, by the placenta. Most frequently the discharge of blood does not cease until the placenta is expelled. (DESORMEAUX.)

16. Abortion proceeding from the more energetic exciting causes is sometimes preceded by pains, and an unusual sense of weight in the loins and at the lower part of the vagina; by horripilations or rigors, by general uneasiness, and cardialgia or nausea. From the first there is often an appearance of blood, followed by the discharge of a sanguineous serum, which soon passes into serious hæmorrhage. In other cases the action of the cause is instantly followed by a large effusion of blood, which continues until after the expulsion of the foetus and its appendages. Frequent lancinating pains dart through the abdomen, chiefly in the direction of the umbilicus and vulva: the uterus makes efforts at expulsion, and the foetus is expelled. The more advanced the term of pregnancy, the nearer do the symptoms approach to those of delivery at the full time; and the nearer also do its consequences assimilate to those following upon a natural confinement, as the lochial discharge, after pains, milk-fever, &c.

17. It is sometimes observed, even up to the middle period of utero-gestation, that the foetus is expelled enveloped in its membranes. But it sometimes also occurs in the first months, that, after the rupture of the membranes, the foetus and placenta are retained, decomposed, and discharged, in the form of a brown foetid sanies. In other cases the placenta is not expelled until several weeks after the foetus, either in the state now described, or in that of a putrid mass. It occasionally is observed that the placenta continues attached to the uterus, and is nourished, increasing in size, and assuming the appearance of a fleshy mass, in which are sometimes found simple cysts, or cysts containing hydatids. This latter occurrence takes place either when the foetus had been expelled, or had died at an early period of its formation; and, whilst it was yet small and nearly gelatinous, being dissolved during the process of decay in the amniotic fluid, or preserved in it.

18. This change in the placenta forms what has been called by DESORMEAUX and others the *mole of generation*; the chief character of which is that it possesses a cavity lined with a smooth membrane, the remains of the amnion. Frequently, at the more advanced periods at which abortion takes place, the foetus is expelled alive; but the duration of its life subsequently depends upon its age, and the circumstances attending its abortion. It sometimes also is dead before it is expelled, occasionally for a considerable time; although it may have reached the age of several months. Its death does not necessarily lead, although it does generally, to its expulsion. In

some cases it is retained even up to the full period of utero-gestation, and is then thrown out in a state of peculiar softening and maceration, but without putrefaction: this only occurs when the membranes have remained entire, and air been excluded from the interior of the uterus. In other instances it is converted into a substance resembling adipocere, or the fatty substances generated during the decomposition of animal matter. In rarer cases the foetus and envelopes become hardened, and even converted into a bony or petrous state, and retained till the natural death of the mother; or, in the course of some months, or even years, occasion inflammation of the uterus, and suppuration. Sometimes, in cases of this latter description, a portion of the uterus forms adhesions to the parts opposite; the abscess which is formed extending in that direction, and opening on the surface of the abdomen, or in the interior of the intestinal canal, or into the vagina, and giving issue to purulent matter, mixed with a foetid sanies, and portions of bones arising from the decomposition of the textures of the embryo. But these latter consequences of abortion are rarely met with unless in cases of rupture of the womb, or extra-uterine impregnation.

19. In some cases of abortion the hæmorrhage from the uterus continues to a serious extent for several days. This may be the case at various epochs of pregnancy; and may result from the detachment, partial or general, of the placenta, and its retention along with the foetus in the uterine cavity, owing to imperfect action of the uterus to eject it. It may also proceed from the expulsion of the foetus, and the retention of the placenta, either altogether or partly separated from the uterus. In some cases the presence of the placenta, or of a portion of the membranes in the womb, or in the os uteri and upper part of the vagina, by the irritation thereby occasioned, may have the effect of keeping up a constant and exhausting hæmorrhage. In a case of abortion to which I was recently called, the practitioner in attendance stated the foetus to have come away two or three days previously. Upon inquiring as to the discharge of the appendages, I was led to recommend an examination *per vaginam*; when they were found lodged partly in the vagina and os uteri. After their removal the patient rapidly recovered.

20. III. DIAGNOSIS.—The diagnosis of abortion should be directed to three objects: 1st, its cause; 2dly, to the possibility of preventing its occurrence; and, 3dly, to ascertaining the stage or development of the process. The causes of abortion are generally readily recognised, and admit of an easy explanation. There are two, however, to which PROFESSOR DESORMEAUX has particularly directed attention; namely, rigidity of the fibres of the fundus and body of the uterus, and laxity of its neck. The former of those is generally connected with a similar state of the whole system, and accompanied with scanty or painful menstruation. In the first impregnations abortion takes place at an early period; but in subsequent impregnations the period of gestation approaches more nearly the natural epoch, the female at last bearing children to the full time. When the abortion is referable chiefly to laxity of the neck of the uterus, a result contrary to the foregoing takes place; the period of abortion approaching nearer, in successive conceptions, to

the time of impregnation. Examination per vaginam discloses this state of the cervix uteri, which sometimes permits the escape of the ovum without much pain. The presumed existence of either of the foregoing states, particularly if any of the symptoms enumerated as characterising abortion be present, should lead us to suspect its approaching occurrence. And it may be considered as commenced if pains occur at regular intervals, which become of shorter duration, and are directed from the umbilicus to the os coccygis; if the os uteri dilates, if the membranes become prominent during the pains, and if the amniotic fluid escape. M. DESORMEAUX, however, has detailed instances where, notwithstanding the above phenomena, the patient was not delivered for several weeks afterwards; but these are extremely rare.

21. In cases where more than one child is contained in the uterus, or where this organ is double, one of the fœtuses may be expelled in the course of gestation, and the other may still remain and arrive at the full period of foetal life. The eminent author whom I have now quoted mentions the case of a female, pregnant for the first time at the age of forty years, who experienced abortion at two months and a half: the symptoms of pregnancy, however, continued, and the motions of the fœtus were felt at the usual time. At the seventh month, a severe fright was immediately followed by symptoms indicating the death of the child; however, the motions of the child were still felt in the uterus: at last, after two months, and at the usual period of gestation, this female was delivered of a dead child, and of another which had arrived at the full period, and was living and healthy. M. ROUSSET also related a similar case (*Traité de l'Hystérotokie*). When abortion occurs during the first two months, we can often only distinguish it from excessive menstruation by the coagulating of the blood. Cases, however, sometimes are met with where coagula form during menstruation, but seldom or never during healthy menstruation. Abortion is most frequent during the first three months of pregnancy.

22. IV. PROGNOSIS.—Abortion has been considered of more serious import than delivery at the full time, by HIPPOCRATES, ÆTIUS, MAURICEAU, and others. The prognosis will, however, entirely depend upon the nature of the causes producing abortion; the period of gestation at which it takes place; and the symptoms accompanying it. It may be stated generally, that the danger increases in proportion as it approaches the full period of gestation; inasmuch as the hæmorrhage is greater, the expulsion of the fœtus and appendages more difficult, and the milk-fever more violent, the longer the period of utero-gestation. The abortion which occurs from accidental, or active exciting causes, is generally more dangerous than that which follows the predisposing causes; this is more particularly the case, the more violent the cause, the more prompt its effects, and when it acts upon females not predisposed to abortion. The most dangerous abortions are those which are procured by substances of an irritating nature taken internally, and by attempts to excite the uterus, or to puncture the membranes per vaginam.

23. On the other hand, when abortion takes

place spontaneously, and without any very manifest or sufficient cause, it is often unattended by pain or difficulty, leaving behind it scarcely any unpleasant consequences; but this form of abortion is most liable to recur; and its repeated occurrence often gives origin to a number of ailments, some of them of serious moment, such as irregular menstruation, chronic metritis, organic lesions of the uterus and ovaria, irritable uterus, hysteria, and a debilitated and cachectic habit of body.

24. Abortion is chiefly dangerous from the hæmorrhage attending it; and hence the risk is proportionate to the extent of this effusion. Abortion, accompanied by convulsions, diarrhœa, dysentery, or supervening in the course of fevers, inflammations, or of eruptive diseases, are seldom devoid of danger, which, under certain circumstances, is even great. Inflammation of the womb of great severity, endangering the life of the patient, or causing adhesions of the Fallopian tubes or of the ovaria to the serous surface of the uterus, and consequent sterility, is not an infrequent consequence of abortion.

25. On the other hand, it may be productive of certain advantages, according to MAURICEAU, DESORMEAUX, and some others, who have, in rare cases, observed abortion occurring before the third month to be followed by a more regular state of the catamenia, in those who had been irregular previously, and by an improved state of health; even fecundity taking the place of former sterility.

26. V. TREATMENT.—The treatment of abortion is divided into, 1st, the preservative; 2d, the palliative; and, 3d, the remedial. On each of these I shall offer a few remarks.

27. i. The *Preservative* treatment comprises the following objects; viz. to remove the predisposing causes as far as this may be accomplished; to repress all undue action whenever it may appear; and to prevent, as well as to counteract, the effects of the exciting causes. These ends are to be kept in view, and applied to individual cases, appropriately to the causes and circumstances by which they are characterised. Where plethora, general or local, exists, it should be reduced by general or local depletion, in very moderate quantity, and repeated at short intervals; but more preferably by a low and antiphlogistic diet and regimen, acidulous and cooling beverages, the recumbent posture, and tranquillity of mind. In cases characterised by relaxation of the system and of the reproductive organs, an opposite, or a tonic and invigorating, regimen is required. In every instance the preservative treatment must be based upon our views respecting the pathological state of the uterus, and of the whole frame at the time of prescribing it.

28. When the horizontal posture is considered necessary, the patient will be more benefited by reclining on a mattress, than on a soft, hot bed. Her apartment should be cheerful, large, and airy; the bed-clothes light; and all anxiety of mind respecting the issue, and depression of spirits, prevented; a confiding and cheerful state of feeling will materially conduce to a favourable result. The *diet*, under ordinary circumstances, ought to be light and digestible, and varied according to the particular circumstances of the case. The *beverage* should be mild, and, in cases of local or

general plethora or excitement, rather cooling than otherwise, and such as may promote, rather than retard, the natural actions of the bowels. Lemonade, imperial, barley-water, toast-water, &c., are amongst the best in this class of cases.

29. Much will depend upon the perseverance with which this plan may be followed, particularly in cases of habitual or precedent abortions; where it ought to be rigorously enforced and continued for months, or, at least, for a long time after the period of gestation at which the former abortion occurred. If the threatened abortion be accompanied with pains, or by any degree of discharge, an opiate should be given at bed-time; and, in every case where we have conceived it requisite to abstract blood, either generally or locally, even as a preventive measure, the operation should be followed by a dose of opium.

30. Attention to the bowels is indispensable; but great discrimination is necessary in the choice of laxatives when the bowels are constipated. These should be of the most cooling and gentle description. The soluble tartar, and cream of tartar in the form of electuary, or with confection of senna, particularly in cases of plethora, are very eligible. Castor oil, with a very few drops of laudanum, which will not retard its operation; or small doses of the bi-sulphate of potash, are also suitable laxatives.

31. When, from our knowledge of the state of the ovum, in previous abortion, we suspect a repetition of it, we may endeavour to prevent it, by using those means which are most successful in imparting energy to the constitution, and, through it, to the generative functions; so that the process of fetation may proceed to a successful issue. This is, perhaps, best accomplished by change of air; the use of the tonic mineral waters, both internally and in the form of baths; but the mineral acids given in the infusions of bitter tonics, or with the solutions of the salts of iron: as the tinctura ferri sesquichloridi; the tinctura ferri ætherea (see *Appendix*); by the sulphate of zinc, with the compound infusion of roses; by the exhibition of the various balsamic and terebinthinate medicines, combined with the pulvis cinchonæ, or the pulvis rhei, and the carbonates of the alkalis, or magnesia; and by attention to the state of the bowels, to diet, and gentle but regular exercise. The balsams most serviceable in cases of this description, as well as in all those characterised by weak and imperfect uterine function, are the balsams of Peru, of Canada, of Chio, and of copaiba; the terebinthina vulgaris, and T. Veneta. STEBOLD recommends the balsamum vitæ Hoffmanni (F. 317.), a medicine which enjoys great reputation on the Continent in many diseases of debility. The loins may be rubbed night and morning, for some time, with the linimentum saponis et camphoræ comp. (F. 306.), the linimentum terebinthinæ compositum (F. 311.), or the liniment. anodynum (F. 298.). The application of the emplastrum cumini, the emplastrum picis compositum, or the emplastrum roborans (F. 118.), to the loins will also prove of service.

32. When diarrhoea occurs during the period of utero-gestation, and more especially if it be accompanied with tenesmus, in delicate females, or in those who have experienced previous abortions, it should be immediately checked or lessened. In these cases disorder is chiefly confined to the

colon and rectum, which should be soothed by small emollient and anodyne enemata, or by the use of suppositories of lead plaster, and opium. Whilst, however, we thus prevent the irritation from being extended from the large bowels to the uterus, we should take care to prevent the retention of hardened fæces in the cells of the colon, by which irritation will be perpetuated; and to remove them, when we suspect their presence, by the use of gentle laxatives, and emollient and aperient injections, avoiding the use of saline purgatives and cathartics.

33. In cases of threatened abortion in debilitated constitutions, the mineral acids, particularly the sulphuric, either with or without small doses of laudanum, or combined with small doses of colchicum, or of digitalis, are extremely useful. Where the circumstances of the case permit the horizontal posture to be dispensed with, the patient may be allowed very gentle exercise, for short periods, in the open air, avoiding all exertion and local excitement. She should live abstemiously, yet not too low. In many cases of this description a glass or two of light wine may be allowed daily, and in several a still more tonic treatment is required. When this is the case, the infusion of calumba, or of quassia, with the carbonate of soda, and tincture of hyoscyamus, has seemed to me very serviceable; and the patient has been allowed the occasional use of the swing, or a gentle ride in a carriage. The tepid and cold hip-bath, particularly with sea-water, are often of use in cases of this description, as well as the treatment recommended in a preceding paragraph. The necessity of abstaining from sexual intercourse, in all cases of threatened abortion, is most evident.

34. In cases accompanied with incipient discharge, either the cold hip-bath, or sponging the hips, thighs, and lower parts, of the trunk with cold water and vinegar; or by squeezing a large sponge filled with cold water, so that its contents may fall in a scattered stream from some height upon the hips and pelvis; will sometimes be serviceable. Injections of cold or iced water, or cold astringent solutions per vaginam, or a lavement of cold water, will sometimes arrest the accession of hæmorrhage.

35. It will occasionally be observed that weak, nervous, and delicate females are often irritable and dispirited from a tedious confinement, during gestation, and even abort owing to this cause; obviously, in many cases, from the effect produced upon the uterus, and upon the nutrition and health of the embryo. This should be anticipated, and prevented by a timely relaxation of the plan, and by allowing the patient as much exercise, amusement, &c., and by adopting as much of the treatment recommended above (§33.), as may be consistent with the accomplishment of our end. When, in these cases, the nervous symptoms predominate, the use of antispasmodics, with anodynes, and their combinations with vegetable bitters, chalybeates, &c., are often required. The diet should also be nutritious; but easy of digestion, and not too heating and stimulating.

36. The foregoing plan will often succeed in preserving the infant, unless the discharge continues or becomes more copious; the uterine pains, with the other symptoms of commencing abortion, still persist or increase; and the woman

be advanced in pregnancy; when little advantage will be obtained, particularly if the orifice of the womb dilate. When this is the case, attempts at preservation will entirely fail, and we must adopt the second intention.

37. ii. The *palliative* measures now required consist, in addition to those recommended (§ 34.), of cold applications to the genital fissure and insides of the thighs, and the *tampon*, or plug, as recommended by a number of authors, and sanctioned by DENMAN, HAMILTON, BURNS, MERRIMAN, DEWEES, RYAN, &c. These are especially requisite where the hæmorrhage is great, particularly when the abortion takes place between the third and sixth month. Opium, with the acetate of lead, given in a very large dose at the first, and repeated according to circumstances, should also be exhibited. Opium, as well as plugging the vagina, are chiefly serviceable where the hæmorrhage continues after the expulsion of the embryo. The plug recommended by Dr. DEWEES is a sponge squeezed out of vinegar. Dr. RYAN advises either old linen or a sponge to be wetted with a saturated solution of alum, and smeared with some oleaginous matter, to be passed up the vagina, so as completely to fill it. Dr. BLUNDELL directs a scruple of alum, dissolved in a pint of water, to be injected into the uterine cavity.

38. The practitioner should in every instance be satisfied as to the expulsion of the embryo and the whole of its appendages, for he may be deceived in this matter (§ 19.); a small remnant of the placenta or of the membranes, when still left in the cavity of the uterus, or even lodged in its orifice, being often sufficient to keep up an exhausting, or even dangerous, discharge. When the embryo only is expelled, the appendages being still retained, or when the hæmorrhage is great, the entire ovum still remaining in the uterus, the erget of rye will often prove of inestimable service; and when given in the form of decoction, with as much borax as it will dissolve, will seldom disappoint our expectations. When a portion of the appendages remain at the orifice of the womb, it may be drawn down by the finger, or by a curved dressing forceps. In cases of great hæmorrhage in the early months of pregnancy, the ovum being retained, Dr. BURNS advises the use of smart clysters, and plugging the vagina. In every case of hæmorrhage from abortion, as well as after delivery at the full period, but particularly when the hæmorrhage proceeds from inefficient contraction of the uterus, and retention of the ovum, or some portion of the appendages of the embryo, I have prescribed with complete success, an enema, with from one to two ounces of the oleum terebinthiæ in a pint of water-gruel.

39. The injection of water into the rectum, or a solution of acetate of lead and opium, has been advised by Dr. DEWEES and Dr. CONQUEST. When the hæmorrhage occurs in robust and plethoric females, and the discharge has not produced much exhaustion, venæsection may be tried. In cases of this description, tincture of digitalis, in half-drachm doses, has been recommended: but, owing to the loss of blood, the effect, although not produced with the necessary celerity, will often be too violent and unmanageable, and will so endanger the patient as not to justify its use unless under very peculiar circumstances. I once prescribed colchicum in large doses in a case of hæ-

moptysis, with violent paroxysms of cough and threatened abortion, occurring in a plethoric lady at the fourth month of pregnancy. Full venæsection was performed, chiefly on account of the severity of the pulmonary disease; the colchicum was directed with an anodyne; and the patient left under the care of the family practitioner. Abortion took place, and was attributed chiefly to the sickness, retching, and depression occasioned by the colchicum; it having been unremittingly administered until my next visit, on the third day from that on which it had been prescribed, notwithstanding the discretionary power with which the practitioner had been invested. (See also, on this subject, the *Treatment of HÆMORRHAGE from the UTERUS.*)

40. iii. The *remedial treatment* of abortions is next to be considered. It occasionally happens that the retention of the ovum, or of a portion of the appendages of the embryo, produces much constitutional disturbance, particularly nervous symptoms and irritative fever, which sometimes assume serious features, with disorder of the bowels, typhoid or ataxic signs, and an offensive vaginal discharge. The decoction of cinchona and hydrochloric acid, or this decoction with the liquor of the acetate of ammonia, or the following, will prove extremely serviceable:—

- No. 1. R Mist. Camphoræ ʒj.; Liq. Ammon. Acet. ʒijss.; Acidi Acetici Pyrolignei ℥ xxv.; Syrup. Zingiberis, ʒss. M. Fiat Haustus ter quaterve in die sumendus.
No. 2. R Camphoræ rasæ gr. ij.—iij.; Extr. Cinchon. Resin. gr. iij.—v.; Conserv. Ros. q. s. ut fiat Pilulæ ij, ter die capiendæ.

In cases of this description a turpentine enema, administered every second or third day, is extremely beneficial: and advantage will be derived from injections of a solution of the chloruret of lime, or of Labarraque's liquor, *per vaginam*.

- No. 3. R Liq. Sodæ Chlorinatæ ʒjss.; Mist. Camphoræ, ʒvijs. M. Fiat Injectio.

41. When troublesome diarrhœa is present, in cases of this description, the chloruret of lime, either in the form of pill or solution, is extremely efficacious. I have prescribed it as follows:—

- No. 4. R Chlorureti Calcis gr. viij.—xviij.; Pulv. Tragacanth. Comp. ʒjss.; Syrup. q. s. M. Fiat Pilulæ xxiv., quarum capiat binas ter quaterve in die.
No. 5. R Chlorureti Calcis, gr. vj.—xij.; Tinct. Calumbæ ʒiij.; Aq. Menth. Virid., vel Aq. Carui, vel Aq. Anethi, ʒvj.—ʒvijs. Fiat Mist. cujus sumat coch. j. vel ij. larga ter quaterve quotidie.

The chloruret of lime may also be administered in water-gruel, as an enema, in doses of viij. to xij. grains, once or twice daily.

42. The debility occasioned by abortions requires the use of tonics, with mineral acids, nourishing but light diet, a wholesome air, gentle exercise, and the tepid or cold salt-water bath:—the mineral waters of Bath, Barèges, or Tunbridge; those of Ems, Spa, Pyrmont, and Geilnau; or the artificial mineral waters of the last-named places, are also beneficial. When nervous or hysterical symptoms supervene, the exhibition of antispasmodics, with gentle tonics, and the occasional use of cooling aperients, are required. The treatment of the effects of abortion is, in every respect, the same as that recommended in the articles on HÆMORRHAGE from the UTERUS, in the unimpregnated and puerperal states.

CLASSIF.—See INFLAMMATION.

1. DEFIN. *A collection of purulent matter formed or deposited in the structure of an organ or part.*

2. An abscess is never an original disease, but is constantly the effect or termination of inflammatory action, in some form or grade, or of irritation of the part in which it is seated. This may not seem to be in accordance with certain phenomena connected with the formation of purulent collections, in parts at a distance from those in which inflammatory action originates, and where pus is originally formed: but I shall have occasion to show that it is not opposed to sound views as to this topic, or, at least, that the exceptions to it are few.

3. Without noticing further than to enumerate them, the older distinctions of abscesses into the warm, phlegmonous, or inflammatory, the cold or congestive, and the acute and the chronic, I shall have to show that, instead of proceeding from different sources, they are equally the result of a certain state of inflammatory action, modified into a variety of forms according to the degrees of vital energy and action of the part, and of the system generally, the organisation of the part affected, and the peculiarity of constitution and diathesis. In the present article, a general view will be taken of the *pathology and medical treatment* of abscess, the consideration of the different kinds of abscess: their various seats, and relations to other diseases, fall under different heads, where they are more advantageously discussed.

4. I. OF THE PATHOLOGICAL CHARACTERS OF ABSCESS.—1st, *Of abscess proceeding from acute inflammation, with integrity of the constitutional energy.*—When a part becomes inflamed, the vitality of which has not been previously injured, as respects either its individual state, or constitutional relations, its temperature becomes increased, and its vessels are injected with a greater quantity of the circulating fluid than in health, and generally in proportion to the violence of the irritation upon which this afflux of fluid depends. At first the fluid does not extend beyond the vessels in

which it has passed; but, in proportion as it distends them so as to exhaust their tone and power of reaction, and as the vital cohesion of their extremities, and of the tissues which they supply, is weakened, a portion of the more fluid constituents of their contents escapes into the texture of the part affected; infiltrates, and combines with its constituent elements, and renders it, at first, more compact and dense. But, at the same time that the inflamed part undergoes this change, it loses its vital elasticity, is more friable or lacerable, so as to break down more readily from foreign pressure, or upon the application of a firm ligature.

5. If the inflammatory action stops not here, the tissues affected by it undergo further changes. They pass, more or less rapidly, from a dense but friable state to that of softening; and this quickly but insensibly assumes a pulpy condition, owing to its continued and increasing infiltration with the more fluid parts of the blood, and even with more or less of its colouring particles; the molecules composing the tissues of the part being so combined with, and separated by, the infiltrated fluid, that all distinct traces of proper organisation are lost. From this pulpy state, to which the central portion of the inflamed structure is reduced, the transition to pus proceeds rapidly. But it is not to be understood that the tissues themselves are converted into this fluid. The fluid poured out from the extreme capillaries gradually distends the surrounding parts, and partially dissolves the softened and disorganised tissues in which it is effused. The coagulable lymph, which the tonic or unexhausted vital energy of the adjoining vessels form in the surrounding texture, confines the effused fluid, and prevents it from extending beyond the barrier it opposes; whilst the impaction of the cellular tissue, occasioned by the increasing quantity of purulent effusion, and the pressure it produces in all directions, with the thickening, and the continued deposition of lymph in the parietes of the abscess, tend still further to fulfil this end, and thus to limit the mischief, and to prevent the contamination and disorganisation of the adjoining structures; consequences which not infrequently supervene, when the vital energies of the frame and the state of local action are insufficient to admit of the formation of coagulable lymph, and to throw up this barrier against the extension of disease.

6. The first step of the suppurative process is the dissemination, particularly in the softest, in the first and most intensely inflamed part, of minute collections of a sero-albuminous or sero-sanguineous matter. By degrees, this fluid becomes more abundant. These minute collections enlarge, approach each other, and, at last, the partitions of softened tissue between them are altogether disorganised and disappear; the whole, at last, forming only one cavity of variable extent. As this process advances, the effused fluid changes from a thin albuminous lymph into pus; which becomes more thoroughly elaborated, losing its colouring matter which it had derived from the blood, and dissolving the shreds or *débris* of the disorganised tissues in which it had formed: and when the suppurative process is matured, the pus forms an homogeneous fluid, presenting certain characters distinguishing it from all other animal fluids.

7. *Pus*, taken from a matured abscess of the description now exhibited, is generally a whitish or cream-like fluid; friable, homogeneous, soft, and smooth to the touch; somewhat heavier than water, in which it is only partially soluble; without any disagreeable smell, and producing of itself no irritating effects upon the tissues enclosing it, as long as it is excluded from the action of the atmosphere. Upon a closer examination, it is found to consist of minute colourless globules, resembling the colourless globules found in the blood, floating in a thin albuminous fluid.

8. It is often a matter of importance to distinguish *pus* from the *mucus* secreted by a mucous membrane in a state of irritation; and accordingly, various attempts have been made to establish some specific character. The circumstance of *pus* sinking in and partially mixing with water, whilst *mucus* remains at its surface, has been taken as a common test; and in many cases will be sufficient, with the history of the disease, and various concomitant phenomena, to enable us to decide: but it should be recollected that the *mucus*, which is frequently secreted in great abundance by the internal surface of the bladder, and which is very remote from *pus* in its characters, always sinks in water. Besides, mucous surfaces, when in a state of inflammation, secrete a fluid varying from a thin watery or frothy matter; and in some cases, from a thick albuminous and viscous *mucus* to a friable cream-like *pus*: but most commonly, a muco-purulent liquid, which presents more or less of the characters of both *pus* and *mucus*. The appearance exhibited by *pus*, when pressed between two plates of glass, which are afterwards separated, is often distinctive: this fluid attaching itself to their surfaces, without the viscous adhesion of *mucus* and partly consisting of small globules. The viscous elasticity of *mucus*, of which character *pus* is entirely deprived, distinguishes the one from the other more completely, and in a more intelligible manner, to the practised eye, than any other feature they present. In addition, however, to this, it may be added that, when water is added to a solution of *pus* in dilute sulphuric acid, a more or less abundant precipitate is formed; whilst, with a solution of *mucus* in the same acid, whitish filaments form on the surface upon the addition of water.

9. As the partitions of softened tissue placed between the incipient purulent collections, in a part undergoing the early process of suppuration, lose their vitality, and become broken down in the effused fluid, the vessels and nerves, as well as the more solid tissues passing through the part, continue to resist the disorganising process for a longer period, so as to form isolated bridges, and communications between the separated parietes of the abscess.

10. The interior of the *parietes* of the cavity is generally more or less reddened, tomentous, and very close in its texture, owing to the impaction or distending power exercised by the accumulated fluid and the effusion of lymph; so that the fluid contained by them is completely isolated from the surrounding structures. The *membrane* thus formed presents all the characters of a mucous surface, particularly when the greyish pellicle which usually covers it is removed. Its interior surface is in contact with the purulent collection; whilst, externally, it adheres intimately to the

surrounding tissues, and is confounded insensibly with them. It approaches more nearly to the circumference of the inflamed part, the more complete the softening of the tissues, and the more the abscess has advanced to maturity. Its density and thickness are generally in proportion to the slowness of its formation and the length of time it has existed.

11. In parts abundantly supplied with cellular tissue, the membrane proper to abscesses acquires a great degree of resistance and density, forming thick *cysts*; whilst in very soft organs, or in those but scantily provided with cellular tissue, as in the brain, it remains long in the state of a vascular pellicle, scarcely distinct from the healthy structure with which it is connected. It is in general rare that we find a thick or firm cyst in the acute abscess now under consideration; for it forms too rapidly to admit of the thickening and condensation usually occasioned by inflammatory action of some duration. In some very acute abscesses, as in those which sometimes form in the liver of Europeans residing in India, after intense inflammation of the internal structure of the organ, no cyst, membrane, or even pellicle can be detected on the internal parietes of the abscess; the whole surrounding structure being inflamed, softened, and sometimes portions of it hanging or floating in shreds in the midst of the purulent collection. In these cases the purulent collection, although existing as a circumscribed abscess, more nearly approaches the diffused abscess next to be noticed.

12. The functions of the membrane lining abscesses are not confined to the containing and isolating the purulent matter, so as to prevent the contamination of the adjoining structures. Owing to the absorption and exhalation proceeding in its surface, the contained fluid is continually renewed, its qualities are modified, and its decomposition prevented. It is not altogether removed from the influence of life, but participates in the vitality of the surrounding textures, as all fluids accumulated in organised parts do, though in a feeble and obscure degree. M. DUPUYTREN remarks, that it is through the medium of this living envelope that the matter contained in abscesses is augmented and diminished in quantity; is thickened, or rendered more fluid; or is occasionally changed by substances absorbed or injected into the circulation. It is because the cysts of abscesses are connected by an intimate sympathy with the chief centres of vitality, that the excitation of the more important viscera affects them in so marked a manner; and that remedies, judiciously applied to these viscera, often tend to promote the absorption of the matter they contain.

13. 2d, *Of abscesses proceeding from acute inflammation in a cachectic habit of body, deficient vital resistance, and with a tendency to spread; or Diffuse Abscess.*—In debilitated and vitiated habits of body; in persons of exhausted vital energy, whose assimilating and secreting organs are torpid; and owing to the operation of certain noxious and intense causes, particularly those which contaminate the structure to which they are applied, as various animal poisons, animal and vegetable matter in a state of decomposition, or whatever produces, from its local or constitutional action, a septic effect upon the living textures—from these circumstances, especially, inflammatory action is

not limited to a particular part, or within distinct bounds; and the fluid which is poured out from the inflamed vessels is not circumscribed, or confined to the centre of the inflamed part. The inflammation which produces this unhealthy and imperfect form of abscess is always characterised by that state of asthenic or ataxic action, local and general, which is incapable of producing coagulable lymph from the blood, that may limit both the morbid action and the effused fluid. (See art. INFLAMMATION.)

14. This kind of abscess not infrequently forms in erysipelas; or after wounds, injuries, and punctures; and from the inoculation of an animal poi-on. The characters of the succession of morbid actions it presents are want of vital power and resistance, and a speedy solution of the vital cohesion of the affected tissues. It would seem that the influence of the ganglionic nerves supplying the capillaries of the part is rapidly, or almost instantly, destroyed by the cause of the disease; and that the vessels, thus deprived of a great proportion of the whole of their vitality, allow the escape of the more fluid parts of the blood, and the infiltration of the tissues. The vessels pass rapidly, and without the previous grades of healthy inflammation, into that state which admits of the effusion of a watery or puriform sanies. The state of vital energy, and the deficient crisis, or unhealthy condition, of the blood itself, probably contribute to this result; and, with the effect of this effusion on the diseased part, promote the rapid exhaustion of the remaining action of the capillaries.

15. Diffusive abscesses generally commence in, and spread rapidly in the direction of, the cellular tissue. They affect also, in a very marked manner, the other structures placed in their way. They seldom commence in the internal viscera, as the liver, lungs, &c.; but when they do thus originate, as is occasionally observed in the latter stages of malignant or ataxic fevers, in exhausted states of the frame, &c., they nearly approach the characters they assume in the cellular structure. In almost every case of this disease, the constitutional disturbance is very remarkable; and the powers of the nervous system, particularly that presiding over the organic and assimilating functions, are uncommonly depressed. Locally, the effusion of a watery, or sero-albuminous, or a sero-sanguineous fluid, is nearly coeval with the affection of the cellular tissue and congestion of its capillaries. The vital cohesion of the inflamed texture is rapidly dissolved; and the fluid, abundantly poured out in its areolæ or cellules, distends the part, diminishes its vital functions to the lowest grade, and, at points, lacerates its tissue, thereby partially cutting off its connection with the adjoining structures. Thus the fluid is effused from the congested capillaries of the affected part in numerous places: in some, forming considerable collections; in others, mere infiltrations. Parts of the cellular tissue itself, and, in rare instances, as the mischief proceeds, portions of adjoining or intermediate textures, are deprived of all vitality, sphacelate, and mix with the fluid effused.

16. In many cases the integuments participate but imperfectly, and often not at all, in the morbid actions, whilst the process, as now described, is going forward; and the great effusion into, and

partial destruction of, the cellular tissue, have enormously distended the limb or part in a diffused manner, and to a great extent, and given it a boggy or imperfectly fluctuating character. At a later period, parts of the more attenuated or discoloured integuments vesicate, ultimately burst, and give issue at first to a discoloured puriform secretion, which afterwards becomes offensive and otherwise modified. When the skin is affected, it generally presents a dark or livid hue: its temperature is seldom above (excepting, sometimes, at the very commencement of the antecedent inflammation), and frequently sinks below, the natural standard.

17. With respect to the appearance of the secretion in this form of abscess, I may state, that it not only varies remarkably in different cases but also at different stages of the same case. At first, the fluid effused and infiltrating the cellular structure consists chiefly of a limpid, reddened serum, which readily flows from the divided structures; in a more advanced stage, the effused matter is less fluid, often high-coloured, but without the whiteness and opacity of purulent matter. Afterwards, the cellular membrane is engorged with a white semifluid matter, which separates the particles of fat and cellular tissue at an unusual distance from each other. In subsequent stages it continues opaque; but often becomes reddish, greenish, and more fluid. At a still more advanced period, the infiltrated cellular and adipose tissue are entirely broken down, and the sphacelated portions hanging into, or mixed with, the puriform matter; which sometimes now presents the appearance of a brownish, purulent sanies, sometimes a greenish pus, and at other times a sero-purulent matter of various shades of colour and degrees of consistence. At no period of the disease is the matter contained in any circumscribed cavity, but is gradually and irregularly lost in the surrounding cellular tissue; without any demarcation, or appearance of coagulable lymph about the circumference of the diseased part. In general, the purulent secretion speedily assumes an offensive odour, and its sensible qualities are otherwise altered, and often variously, upon the admission of air to the diseased surface.

18. The muscular structure, and other parts in contact with the puriform matter, and in the way of the spreading disease is generally much discoloured, softened, easily torn, and sometimes partially destroyed. In some cases the muscles are paler, in others darker, and more livid, than natural. In rarer instances, the adjoining bones and more resistant structures are also affected. (See INFLAMMATION, Diffusive.)

19. 3d, *Abscesses consequent upon inflammation of lower grades of intensity.*—The more slow and obscure the progress of inflammation, the less marked are the signs of irritation preceding and accompanying abscesses. It is not uncommon to observe, in lymphatic and phlegmatic temperaments, fluctuating tumours of various sizes, both superficial and deep-seated; without any considerable pain or increase of animal heat, either antecedent or subsequent to their formation. Purulent collections, of a chronic and indolent character, generally proceed from a low but continued state of irritation, or from reiterated excitation of so low a grade as scarcely to influence the sensibility of the part; and occur in constitutions of weak vital

resistance and defective restorative energy. On the other hand, the abscesses described in the preceding sections result from inflammation of a more or less acute character, occasioned by active stimulation or deleterious agents, and generally affect the system in a more or less active manner.

20. Owing to the low grade of irritation in the affected part, the vessels are but little, and often scarcely perceptibly, injected. The abscess, in place of commencing with a number of distinct centres or foci, appears at first as a single isolated collection in one or more of the cellular areolæ, and presenting, from the commencement, a manifest fluctuation. In some cases, this appearance of the affected part is less than of true phlogosis than of a deviation from its nutritive actions. The tissues, instead of attracting, in virtue of their vital endowment, the nutritive particles; and the vessels, instead of imparting them in an appropriate condition, and exhaling a fluid suitable to the healthy state of parts,—are so far changed as to fail in the performance of these actions; the vessels furnishing a fluid of a certain kind, apparently composed of the particles or globules which, under the influence of healthy vital endowment, would have been separated from the circulating fluid for the nourishment or growth of the tissues, and of the watery exhalation destined to lubricate them, and render them fitted for their functions.

21. In the chronic varieties of abscess, the *pus*, being secreted under the influence of a lower grade of excitation, differs from that previously described (§ 7, 8.). It is frequently yellowish, serous, transparent; containing flocculi of an albuminous or fibrinous nature, and whitish, opaque appearance: sometimes it is mixed with minute shreds of cellular-like substances. In other cases it is nearly analogous to mucus, from its thickness and viscosity. In some subjects, when very slow in its formation, it assumes a greater consistence and opacity, resembling half-congealed lard or liquid honey; and the tumours which it forms seem to constitute a connecting chain between pure abscesses and melicerous or steatomatous cysts. These latter differ in no respects from abscesses devoid of active inflammation, but in the greater consistence of the matter they contain: and in some cases, as M. DUPUYTREN remarks, it is difficult, if not impossible, to distinguish between them.

22. Owing to the extreme slowness of their formation, and the absence of acute inflammatory action, the *parietes* of the present kind of abscess have a more distinct organisation than those of the first species. Vascular injection and redness are here seldom observed exteriorly to the *cyst* enclosing the purulent collection. The skin covering the tumour, and through which the fluctuation is readily felt, is generally free, moveable, and unaltered. All the morbid action seems concentrated in the diseased membrane enclosing the matter. This membrane or cyst is, internally, of a reddish grey tint, and more or less intimately connected with the surrounding structure. It is in some cases soft, thin, and cellular; in others, thick, strong, and of a cellulo-fibrous, or even fibrous, structure. The slower the tumour is in enlarging, the more liable is the cyst to undergo change, and to modify the state of the matter it contains: and, hence, abscesses of a very slow or chronic kind often approach slowly but nearly

to the characters of several other encysted tumours.

23. The purulent collections which form around foreign bodies, that occasion but little irritation, generally belong to the present kind of abscesses. They are always lined with a firm cellular cyst, analogous to that enclosing the foreign body itself. The abscesses which proceed from bodies occasioning great irritation are preceded by great pain and inflammation, and belong to the preceding kind of abscess.

24. 4th, *Of symptomatic abscesses, or collections of matter at a distance from the places where the pus is first formed.*—In the foregoing sections I have considered the formation of abscesses in, and their limitation to, the primary seat of irritation: but if the parts affected are surrounded by a loose areolar cellular tissue, readily permeable by the matter as it is formed; and especially if the state of vascular action and vital energy of the frame are insufficient to the production of coagulable lymph around the inflamed centre; the matter gradually finds its way in the course of the cellular structure to adjoining parts, particularly to those which are more dependent, infiltrates them, and forms more or less distinct and fluctuating tumours at a distance from the primary seat of inflammation. Instances of this kind of abscess are furnished us in diseases of the hip-joint, and in cases of inflammation commencing in some or one of the vertebræ, or their fibro-cartilages. In this latter case, if the disease commences in one of the dorsal vertebræ, the purulent fluid may accumulate under the pleura, infiltrate the adjoining cellular tissue, and, following the direction of the ribs, appear at some part of the side or back, or even near the sternum, far from its origin. When the inflammation attacks one of the dorsal or lumbar vertebræ, or intervertebral structures, it may travel in a similar manner behind the pillars of the diaphragm, proceed in the course of the *psosæ* and *iliacæ* muscles, following the cellular tissue behind the peritoneum, and appear exteriorly, most frequently under the crural arch, but sometimes through the inguinal ring. In other cases it proceeds to a shorter distance, and points at the sacro-iliac symphysis, or in the angle between it and the spine: or it may extend down the pelvis in various directions, following the cellular substance surrounding the vessels and nerves. Thus it may pass through the ischiatic notch, forming an abscess at the internal part of the gluteal muscles; or along with the great sciatic nerve, and point on the superior and posterior part of the thigh; and, lastly, it may find an issue in the perineum, at the margin of the anus, or into the rectum, or even into the vagina. In some rare instances a double tumour and opening are formed. In the case of a female by whom I was consulted, the matter had found its way to the integuments of the sacro-spinal angle of the loins, where it was punctured by a surgeon, and yet had also burst its way into the vagina. In the case of a groom whom I attended, a tumour formed at the sacro-iliac symphysis, below the crural arch, producing the most violent and painful tumefaction of the limb, owing to the pressure of the matter on the nerves and veins; and the matter afterwards burst into the lower part of the sigmoid flexure of the colon.

25. The matter proceeding from abscesses symp-

tomatic of inflammation and ulceration of bones or cartilages is generally greyish, thin, mixed with albuminous flocculi, minute clots of blood, and portions of phosphate of lime. It exhales a nauseous odour: but this characteristic is present only after the opening of the tumour, and when the air has access to the cavity.

26. If we examine the cavities of symptomatic abscesses, and trace them from their origin to their outlet, we shall find, in the former situation, the cartilages and bones profoundly changed: the bones are softened, friable, changed to a greyish black, partially absorbed and carious, and their periosteum destroyed. From this origin of the disease is formed a channel or sinus, traversing the cellular structure frequently in the course of the large vessels or muscles, and terminating with the external outlet of the tumour. The whole of this canal or sinus is usually surrounded by a softened, friable, or lardaceous state of the textures; and lined with a smooth, thick, firm, cellular, or fibro-cellular membrane, which in some cases is of a fibro-cartilaginous structure. At the lower part, the canal generally dilates into a considerable cavity, sometimes irregular or sinuous in its form, and lined with the membrane usually found in the more chronic kinds of abscesses.

27. 5th, *Of consecutive abscesses; or collections of matter found in situations consecutively to its formation in distant parts, between which there exists no communication.*—It has been not infrequently remarked, that inflammation of a part has taken place, and has gone on to suppuration; that the matter thus formed has been absorbed; and that it has subsequently formed in some other viscus, generally in an internal organ. The nature and procession of the morbid phenomena now enounced have led to some inquiry, particularly in recent times. The circumstances in which consecutive abscesses occur in practice are the following:—

Inflammation of the internal surface of the uterus, or of its veins, or of both the substance of the uterus and veins, occasionally takes place after child-birth, and terminates the life of the patient. On dissection, purulent infiltrations or distinct collections of pus are found, in one case, in the lungs; in another, in the liver; in a third, in the substance of the brain; in a fourth, in the capsules of the joints; and, in a fifth, in both the lungs, liver, and perhaps, also, in the joints. A man, from injury of the head, has inflammation of the sinuses of the brain, followed by all the symptoms of a vitiated state of the circulating fluid, terminating in death; after which, abscesses, or purulent infiltrations, are found in the liver or lungs. A similar procession of phenomena occasionally results from phlebitis consequent on blood-letting, or other causes; also during the suppurations following amputations, particularly when the matter is confined on the face of the stump, by the adhesion of the integuments which had been drawn over it. A child is seized with severe or confluent small-pox; and during, or subsequently to, the secondary fever, fluctuating tumours form in the joints from matter accumulated in their capsules. Upon dissection, the cartilages are found eroded; and, in other rare cases of this kind, purulent collections are found in the internal viscera. In other instances, abscess disappears from external parts; the patient

sinks with low fever; and, upon dissection, collections of pus are found in internal organs. In cases of this description, the following require notice:—1st, The state of the vital energies preceding or during the occurrence; 2nd, The symptoms characterising the progress of the phenomena; and, 3rd, The nature of the results.

28. 1st, The energies and vital resistance of the system are generally greatly impaired, either from pre-existing or concurring causes, in cases where consecutive abscesses form. (See article on *Inflammation of VEINS.*) 2nd, The depression of the powers of life increases as the disease advances. The nervous system is seriously affected; the circulating fluid betrays change in its appearances, after its emission, or after death; the soft solids lose their vital elasticity and cohesion; the surface of the body and countenance become dusky and livid; and low delirium, rapid and weak circulation, &c. take place. 3rd, The purulent matter is generally either infiltrated into the parenchymatous structure of some organ, or collected into one or more distinct abscesses, or it is effused into the cavity of one or more joints. When the matter is infiltrated into the texture of an organ, the infiltrated structure is very frequently also softened. The purulent collections that are found in other cases generally have no distinct cyst, and the surrounding substance of the organ seldom presents any marked redness or injection of its vessels, or indeed any remarkable change, excepting in some instances a slight softening. The matter is usually found in several distinct abscesses or collections, varying from the size of a small seed to that of an egg, or even larger. Sometimes the immediately surrounding structure seems impacted around the abscess, but not otherwise changed. The purulent matter itself varies but little from that which is observed in the abscesses described in the first section. (§ 6, 7, 8.) It is occasionally of a darker or greenish hue, particularly when found in the liver.

29. As to the *Origin* of these purulent collections some doubts may be entertained. That they are very intimately connected with the primary inflammation and formation of matter in other parts of the system, cannot be doubted, but in what way cannot be so readily stated. It seems to me extremely probable, from the attentive observation of the progress of a number of such cases which have come before me in practice, that, owing to depressed vital energy, and deficient resistance of the frame, purulent matter passes into and vitiates the blood; that the morbid condition of the circulating fluid, thus induced, depresses still lower the already weakened nervous powers; and that the irritating matters carried into the circulating current change the state of the capillaries of parenchymatous and some other organs, so that they secrete purulent matter without any evident sign of previous or accompanying inflammation. Several French pathologists suppose that the purulent matter conveyed into the blood circulates without combining with it, and is merely deposited by the capillaries, or separated by them, from this fluid in parts; the vessels and texture of which are most disposed to permit its elimination, or the best constituted to admit of its deposition. It is difficult to determine in which of those ways the consecutive abscess is formed. Indeed, both may approximate

the truth, the consecutive formation of pus arising, in one case, from the irritation occasioned by the presence of morbid matters in the blood; and, in another, chiefly from the separation or secretion of it in the parenchyma of an organ, without any previous or attendant irritation.

30. II. OF THE PROGRESS AND TERMINATIONS OF ABSCESSES.—At any period of its existence, and the inflammatory action in an abscess may cease, and the matter which has been formed be *absorbed*. In these cases the purulent matter is carried into the circulation; and, whether the inflammation is primarily and gradually extinguished in the abscess, or whether intense pain and inflammation, developed in some other organ, exercises on the first centre of mischief a true revulsion, the absorption of the pus is only consequent upon the subsidence of the local signs of inflammation and congestion. The part loses its turgescence, redness, increased heat, and tumefaction, and is restored to its healthy state without any deformity or cicatrix. In these cases the absorbed matter is eliminated from the circulating mass, without accumulating in it to a hurtful extent, by the active or unimpaired functions of the various eliminating organs, particularly by the kidneys, and mucous surface of the intestinal canal, — the matter, in some cases, being apparent in the urine, and in the others exciting a temporary diarrhœa.

31. In other instances, the inflammation productive of suppuration being but slight, or being less completely dissipated, and the solid tissues, and particularly the firm and thickened cyst, opposing the extension of the abscess, it occasionally rests long stationary. In this case the pus remains inactive and inoffensive in the part, like a smooth and inert body lodged in a cyst. Abscesses will sometimes continue for a very long time unchanged, and without occasioning much disturbance to the economy, particularly when deeply seated. In such cases the cyst becomes more and more firmly constituted, thickened, and changed from the state of the surrounding parts; so that the pus is in some measure isolated from the adjoining structures: in this state it may remain, as in the brain and liver, for a considerable time, without any very marked symptoms, until some accident or exciting cause occurs to affect it and the adjoining parts, when the usual course of the disease will be resumed.

32. The foregoing changes are comparatively rare. In the great majority of cases, pus distends, compresses, and obscurely excites, the parts in which it is lodged. Instead of being diminished, the abscess is increased in size, and tends to find an external outlet, uniformly in the direction of either the cutaneous or one of the mucous surfaces. Purulent matter is thus submitted to the general law of the economy; the vital resistance, opposed to all substances calculated to excite or otherwise injure the textures, detaching it by a regular procession of phenomena, as long as the energies of the system are not entirely overwhelmed, to the nearest or most unresisting part of the surface, and at last expelling it altogether from the body.

33. The succession of morbid phenomena occasioning the deliverance of the system from collections of matter is of great importance to the practitioner, particularly as respects deep-seated or internal abscesses. Generally the quantity of

matter is continually increasing, owing either to the extension of suppuration in the inflamed part, or to a continued secretion from the internal surface of the abscess, or to the concurrent operation of both causes. In consequence of this increase of quantity, the parietes of the abscess are distended and applied more closely to the surrounding parts, which are pressed outwards by the accumulated matter. This distending power is equally exercised from the centre to the circumference. But, as all the adjoining parts do not exercise the same degree of resistance, the abscess extends in the direction of the external or free surfaces; its more deeply seated parietes being sustained by all those parts which are placed beneath them; whilst the tissues which are exterior to it, being deprived of aid, are readily elevated and distended by the increased effusion.

34. As to the nature of this effusion, and the changes it undergoes, certain questions have been urged. It has been supposed that the matter found in abscesses is not secreted in the state in which it exists at the period of maturation: but that the fluid effused is in a state which may be called albuminous serum; which, owing to the continued exhalation and absorption taking place in the internal surface of the abscess, is changed into what is called well-digested pus. Others suppose that the purulent fluid is secreted in the state of pus, or nearly approaching to it, by the membrane forming the cyst, and which, as it presents many of the characters of mucous membrane, may, like this membrane, when highly inflamed, secrete a purulent fluid. It is extremely probable that both views may be in a great measure correct: for attention to the maturative process in recent abscesses shows that the fluid first effused is not pure pus; and it is undeniably proved that the matter contained in the different kinds of abscesses is variously modified according to their duration, their situation, and the circumstances attendant on their progress. Whilst, on the other hand, it must be conceded that the internal surface of an abscess, particularly in a high state of inflammation, or when irritated by the contact of the air, will secrete a purulent fluid, or a matter which very rapidly assumes the puriform character; the vessels terminating in it giving issue not only to the watery part of the blood, but also to many of its smaller globules, so as readily to form a pure pus, which quickly becomes thick, upon the evaporation or absorption of a portion of its more fluid constituents.

35. Another important matter, relative to the progress and external pointing of abscesses, is the fact, that inflammation generally seizes upon the adjoining structures, as the internal membrane is more closely applied to them. The parts most distended and stretched by the contained fluid have the inflammatory action extended to them from the parietes or membrane of the abscess. To the inflammatory irritation thus induced in the surrounding textures succeed their adhesion to the parietes of the abscess; absorption of their solid elements, with attenuation; and, lastly, ulceration, — the integuments merely often resisting for a considerable period the discharge of the fluid.

36. If we take as an example the not unfrequent occurrence of abscess in the substance of the liver, and trace its progress in one of those

directions which it sometimes follows, namely, through the diaphragm and lungs, until it empties itself into the bronchi, we shall find the following to be the course of the morbid phenomena:—As the inflammatory action and the secretion of purulent matter proceed, the abscess which has been formed, generally in cases of this kind in the convex part of the organ, advances towards the surface; the inflammatory action extends to this part; and lymph is thrown out, which, with the pressure of the swelling and pointing of the abscess, irritates the peritoneal surface of the diaphragm, inflames it at the part opposite, and occasions its agglutination at this situation to the parietes of the hepatic abscess. As the tumour points upwards, the inflammatory action advances in the same direction; extends to the muscular structure of the diaphragm, which is softened and attenuated, assuming at the same time a dark or bluish tint; and invades the diaphragmatic pleura, where it throws out coagulable lymph. This secretion occasions irritation and inflammation in the opposite part of the pulmonary pleura, and the cohesion of the lung to the diaphragm at the part where the collected matter is advancing prominently upwards. As the parts thus successively involved undergo the softening process consequent on inflammation, and yield before the pressure of the accumulated fluid, owing to their diminished vital cohesion, absorption commences and proceeds in the central or prominent part of the tumour; and the matter thus finds its way in the direction which is most yielding, where the inflammatory action most readily advances, and where the resistance to it is thereby still further diminished. I have had frequent occasion to trace the above phases of the progress of large and deep-seated abscesses; and to satisfy myself that they proceed in a similar manner, whether they advance to the external surface of the body, or open upon a mucous surface, or into a shut cavity; which last is a rare occurrence.

37. It is of importance to observe the procession of phenomena now stated; inasmuch as the successive reddening, inflammation, adhesion, softening, and absorption of the various structures, as the tumour advances exteriorly, are the guides to a very important part of the treatment of these formations. Thus, when we observe marks of inflammatory irritation of the skin take place in the situation of an internal abscess, we may infer that the ulterior phenomena now enumerated, particularly adhesion, have taken place in the parts beneath, and we may safely decide upon carrying an incision from the centre of the inflamed integuments to the seat of abscess.

38. It must not be overlooked, that various aberrations of purulent collections take place, in their progress to the surface, and that they often proceed in a direction opposite to that of gravitation, owing to the resistance of bones, fasciæ, and aponeuroses; which last oppose them in a most remarkable manner, and cause their extension in various directions, giving rise to the most severe local and constitutional sufferings.

39. Abscesses, besides, cause the inflammation of parts placed between them and the centre of the system, as respects the direction of the circulating vessels, as well as of those parts situated exteriorly to them, although in a much less degree, and followed by very different results; for, in-

stead of the thinning, erosion, and ulceration of the exterior parts, tending to advance them to the surface, the inflammation of the parts behind, or more deeply seated than they, is frequently accompanied with thickening, and increased density of structure; whereby the system is, in a great measure, protected from their extension to more internal and vital parts. Numerous instances occur, where the periosteum or the peritoneum, the pleura, the fibrous and synovial capsules, undergo a marked thickening, opposing thereby an increased obstacle to their extension in that direction, when abscesses form in the vicinity of those membranes. When, however, the energy of the system and its vital resistance are deficient, exceptions sometimes occur to this rule, and abscesses find their way, when situated favourably, to this mode of termination, into important cavities and organs. Thus, an abscess seated deep in the parietes of the chest or abdomen, may open into these cavities, as in the case of the son of the eminent M. PETIT; or an abscess in the liver may find its way into the pericardium. But any disposition to its opening internally, is opposed not only by the thickening of the serous and other membranes, &c., as here instanced, but also by the support of the viscera underneath, which resist the pressure and extension of the tumour in this direction.

40. The progress and *spontaneous opening* of abscesses, advancing in the manner now explained, terminate with the erosion of the integuments, which, having been reduced to a pellicle, have their epidermis elevated in the form of a phlyctena, which soon breaks, and gives issue to a portion of the contents of the abscess; and the discharge is renewed at intervals, by the gradual retraction of the parietes of the cavity upon the re-accumulated secretion. The successive evacuations occasioned by the reaction of the parietes of the abscess, are particularly favourable in cases of large abscess, by preventing any vacuity. In cases of empyema, for instance, where the artificial opening is often fatal, a favourable result not unfrequently follows a spontaneous and successive evacuation of the purulous collection: for it is chiefly by imitating the natural process in those cases, that we secure the greatest advantages to the patient, where we find it requisite to open symptomatic abscesses, as those usually called lumbar; and not by making large incisions, and producing a large evacuation, whereby the air has access to their cavities, but by successive punctures, the margins of which are immediately closed, upon the evacuation of that part of the contents which are first expelled by the reaction of their parietes.

41. The passage of air into the cavities of abscesses is always followed by an increased state of irritation of their lining membrane. The hurtful effects of this communication have been demonstrated by M. DUPUYTREN, and other eminent men, although denied by others, but without either the satisfactory proofs of experience or of reasoning. In some cases the accession of inflammatory action in the part, upon the access of air, is very remarkable. In cases of small chronic abscesses this effect is often beneficial; but in large and acute abscesses the irritation thus induced may be too great for the powers of the system to withstand.

42. Under the most favourable circumstances, the effects of the admission of air into the cavity of an abscess are counteracted by the accompanying treatment; and the discharge soon assumes a different appearance from that of the matter first evacuated; it becomes less white and consistent; and, subsequently, when the parietes commence forming the adhesions which precede cicatrization, it is merely a more or less copious citron-coloured serosity.

After the opening of slow and indolent abscesses, the serous, thin, and flocculent pus, with which they are filled, is replaced by the discharge of a more digested, homogeneous, and cream-like fluid, indicating a more intense state of action in their parietes.

43. Upon examining the interior of abscesses which have been opened, it will be seen that their parietes gradually discharge themselves; that they cast off the greyish and flocculent pellicle which covers them; and that they become covered with cellular and vascular granulations, of a lively red and solid appearance, formed from coagulable lymph thrown on the inflamed surface, into which new capillary vessels shoot, and resembling the granulations on the surface of wounds from which is exhaled the matter which succeeds to that first discharged from them. The parietes thus cleansed contract towards their centres, and in the direction of their most deeply seated parts. They afterwards unite; so that the cavity, which has been thus circumscribed, at last disappears. In the situation of the abscess nothing is found but its cicatrix; at first consisting of a cellular lamina, or plate, of various thickness and density, penetrated by coagulable lymph, and subsequently converted into a scarcely apparent cellular line, which sometimes, at last, entirely disappears.

44. But the progress of abscesses after they have been opened is not always so favourable. It may be premised, that the irritation proceeding from the contact of air with the internal surface of an abscess is, in general, in proportion to its volume, and the unyielding state of its parietes. When the abscess is small, the resulting irritation is but faintly marked; but if the parietes be of a large extent, and if the abscess is deeply seated, particularly if it be in any of the viscera, the inflammatory excitement occasioned by the air not only increases all the local phenomena, but also gives rise to serious constitutional disturbance, often terminating the life of the patient. The yielding state of the parietes, and their apposition, are sometimes calculated to counterbalance the bad effects occasioned by their extent. When the diseased surfaces have been freed by the complete discharge of matter, and admit of being closely applied to each other, the admission of air is in a great measure prevented, and adhesions frequently proceed rapidly. Where, however, the parietes cannot be brought closely together, and the cavity can be obliterated only by means of granulations formed to an extent that may fill it, the duration of the suppuration is prolonged, and the effects produced on the constitution by the extent of the discharge are often serious.

45. But this is not all the mischief resulting from the access of air to the cavity of an abscess: the pus which still remains, particularly in deeply seated abscesses, is more or less changed by it,

and exhales an infected or putrid odour, proceeding from decomposition occasioned by the temperature to which it is subjected, and its contact with atmospheric air. It is also often observed, that when large abscesses are opened, and air gains access to them, the morbid excitement thereby occasioned in their parietes re-acts upon the principal vital centres; the nervous systems, the digestive organs, and the circulation suffering from and participating in it, and the suppurative process, is thereby greatly increased; at the same time the constitutional powers are much depressed, the matter is rendered much more offensive, and otherwise changed, according to the seat of the abscess. As the powers of life sink under the disease, the fluid secreted is more offensive and disposed to decomposition, until it is often doubtful whether the change proceeds more from the access of air, than from the low state of vital energy. Indeed, in many cases, the latter cause seems much more influential towards producing this state of the discharge than the presence of air; for we not infrequently observe, that as long as the constitutional powers remain but little depressed, the access of air has but little effect, the discharge exhaling no offensive odour; but as soon as, owing either to the increase of inflammation in the cyst, or to other concurrent causes, the febrile commotion is increased, and the nervous system and digestive organs evince serious disturbance and loss of energy, the discharge becomes rapidly offensive and increased in quantity; the matter often changing from more or less pure pus to a state approaching to putrid sanies.

46. III. OF THE DIAGNOSTIC SIGNS OF ABSCESS.

When inflammation has attacked a cellular structure, or viscus, in which this tissue is a prominent constituent part, and particularly if it be intense in degree, rapid in its progress, and accompanied with a pulsative pain, we may with confidence decide upon suppuration being about to take place. This result is announced by a diminution of the pain, which changes to a pulsatory sensation isochronous with the pulse; by a feeling of weight and tension in the part; by a diminution of the febrile action, succeeded by a large, broad, open, soft, or undulating pulse; and by irregular chills or rigors, which extend, after various intervals, along the back, loins, and sometimes the lower extremities. If the matter is not soon afterwards evacuated, the symptoms of chronic irritation succeed; especially small and frequent pulse, heat or burning of the palms of the hands and soles of the feet; irregular fits of perspiration, and night sweats; loss of strength, and all the characteristics of hectic fever, which makes more or less rapid progress, and is sooner or later followed by colliquative diarrhœa, according to the seat and extent of the abscess, the constitutional powers of the patient, and the treatment employed. The above symptoms indicate that a permanent cause of irritation, and of constitutional contamination, has succeeded to the state of active inflammation.

47. The tumefied state which characterises œthenc or phlegmonous inflammation is greatly modified after suppuration has advanced. It becomes less diffused, is much lessened in the circumference of the periphery of the tumour, and seems more and more concentrated. Hence it

becomes more elevated, prominent, and softened at the centre of the surface. The redness and tension undergo a similar change. The circumference of the inflamed surface is restored in some degree to the natural state; but the more prominent part acquires a dark red tint, afterwards a bluish hue, and yields more and more to the pressure of the subjacent pus. For some time previous to this stage the tumour evinces a more or less distinct fluctuation when suitably examined, and this sign becomes more manifest as the abscess advances to the surface.

48. When an abscess forms in deep-seated parts or viscera, particularly those protected by solid envelopes, or by thick and unyielding structures, the diagnosis rests entirely upon the nature of the constitutional disturbance, and the disorder in the functions of the affected organ or part, and here the physician should seize and appreciate the slightest difference taking place in the pulse, the animal heat, and the state of all the natural and organic functions. In these cases he requires the most exquisite tact for examination in order to arrive at an accurate opinion. The symptoms which should guide him in cases of this description will be stated when I treat of the diagnosis of the different kinds of visceral abscess. I may, however, remark at this place, that even in parts much less deeply seated, when the cyst of an abscess is greatly distended and very tense, fluctuation generally is extremely obscure, or even not to be felt, although its contents may be very fluid. Also, when the purulent matter is contained in no distinct cyst, but is disseminated through the textures, or infiltrated between fasciæ or muscles, or is confined beneath aponeuroses, great uncertainty may exist as to its formation. The parts in such cases present more of a diffused œdema than of a fluctuating tumour; and if fluctuation can be at all felt, it is only obscurely.

49. It must be evident that the more feeble and latent the phenomena of the pre-cursory inflammatory irritation, the more difficult is it to determine the period at which the elaboration of pus commences. We frequently observe in practice, particularly after phlebitis, injuries of the head, fractures, and capital surgical operations, abscesses form in the liver, mediastinum, lungs, kidneys, or ovaries, preceded merely by obscure and occasional pain, and furnishing no certain symptoms of a local kind, by which we can decide as to their formation, until the time that they appear externally, or are detected upon *post mortem* examination. In cases of this description, the constitutional symptoms are our chief guides; but even these are often so uncertain and so imperfectly developed as to leave us in doubt. The accession in this obscure manner of internal abscess is particularly remarkable as respects those which supervene on inflammatory disease existing in other parts, particularly to phlebitis, and which I have denominated *consecutive abscesses*. (See VEINS — *inflammation of*.)

50. Symptomatic abscesses generally escape detection until they advance externally. Previous to this, pain, uneasiness, tumefaction, &c., are only felt chiefly in the part originally affected. But the symptoms already noticed (§ 46—48.), especially the unhealthy aspect of the surface, the state of the febrile action and of the pulse, the

night perspirations, the disorder of the respiratory and alvine functions, will generally serve, in conjunction with the changes in the part to which symptomatic abscesses extend, to indicate the nature of the mischief.

51. It is important, as M. DUPUYTREN has very justly remarked, to take into account, when determining the existence of abscess, the greater disposition inherent in some constitutions to form purulent matter. In some persons, the least irritation is followed by the suppurative process. This is particularly the case in persons of a pale visage, of a soft flaccid state of the different structures, and of the lymphatic temperament. It is also remarkable in those whose vital energies have been lowered by previous disease; by chronic affections of the digestive mucous surfaces; and by those diseases which require the performance of amputation, or other important surgical operations. When the suppurative process has continued for some time, and has afterwards been suddenly stopped by an operation, or any other active treatment, the disposition to form abscesses is generally remarkable. A similar remark may be extended to the sudden suppression of any accustomed secretion or discharge. The most familiar instance of this kind is noticed in the breasts of nurses, which are extremely liable to suppuration upon interruption to the secretion of milk. These considerations should have their due weight with us when estimating the signs of the existence of internal abscess. Those symptoms which are peculiar to collections of matter formed in each of the internal viscera are pointed out in their respective articles.

52. IV. OF THE PROGNOSIS OF ABSCESS. The danger from abscesses is in proportion, 1st, to the extent of their internal surface; 2d, to the depth at which they are seated; 3d, to the indolence of their action, or the deficiency of vital action accompanying them; 4th, to the severity and danger of the disease by which they have been occasioned; 5th, to the sinking or deficiency of the constitutional powers under them; and, 6th, to the severity of the symptoms accompanying them, or produced by them. These positions are so obvious, that no remarks need be offered in support of them. I may, however, observe, that abscesses seated in internal viscera are always attended with danger; but the degree of danger will depend upon numerous circumstances connected with their seat, the direction which they take, the state of the vital energies of the frame during their progress, the chances of their evacuation, and the means of reparation and renovation the constitution may still possess.

53. The prognosis of chronic, symptomatic, and consecutive abscesses depends as much upon the nature of the preceding disease, as upon the state of the abscess itself. In chronic abscess, the danger is in proportion to the extent of the surface of its parietes, and to the grade of constitutional vice. In symptomatic abscess, the danger depend almost wholly upon the nature and extent of the original disease, of which it is the consequence, and upon the largeness of surface extending thence to the ultimate limits of suppuration. In consecutive abscess, the danger is extreme; owing, in many cases, to the nature of the primary disease, the depressed state of the constitutional powers, and to the vitiation of the circulating

fluid and soft solids of the body, with which it is connected.

54. V. OF THE MEDICAL TREATMENT OF ABSCESS. — The indications of cure which we propose in abscess are, 1st, to remove the purulent collection from the part containing it; and, 2d, to procure the obliteration of the cavity in which it was lodged. The first intention is accomplished either by procuring the absorption of the purulent matter, and its elimination from the body; or by opening the parietes of the abscess, and thus giving a direct outlet to the contained matter. When the means used to accomplish the absorption of the purulent matter fail, or when the character of the abscess and state of the frame forbid the employment of these means, opening the abscess must be resorted to when the proper period for having recourse to the measure arrives.

55. 1st. Means which may be resorted to, in order to procure the absorption of the purulent matter, and its elimination from the frame. — Numerous instances have occurred of the rapid absorption of the matter contained in an abscess, and of its discharge from the circulation, 1st, by the urinary organs, the urine becoming abundant, and containing either a puriform secretion, or being otherwise altered; 2nd, by the mucous surface of the bowels, attended with diarrhoea; and, 3d, by the cutaneous surface, in the form of a copious, thick, or viscid, and offensive perspiration. These are the most common channels of elimination of the purulent secretion, when absorbed into the circulation from the cavity of an abscess. The purulent collection may, also, disappear in consequence of other critical or accidental evacuations; but this result is of rare occurrence, and is a much more remote contingency than those enumerated. Experience having shown the possibility, and the great advantages, of removing the matter contained in an abscess by exciting absorption, the means most effectual in attaining this end should be first put in practice.

56. With this view, drastic purgatives may be prescribed, when the state of the patient admits of them, and next to them, such diuretics and diaphoretics, as may be appropriate to the circumstances of the case. Contemporaneously with the use of those internal derivatives, external applications should be employed, particularly those which possess discutient, resolvent, and styptic properties. Frictions with stimulating substances, as ammoniacum, iodine, iodide of potassium, &c.; cold, warm, or tepid affusions on the part, either of simple or mineral waters, or of sulphureous or saline, natural or artificial, may likewise be tried conjointly with the internal means. But this energetic plan of treatment, — this combination of the revulsive and discutient practice, — this *methodus tertiaratrix*, is not applicable to all cases. There are many circumstances connected with the seat and condition of an abscess, and with the state of the different functions, that either altogether forbid its employment, or require important modifications and adaptations of it.

57. Thus, abscesses preceded by acute or active inflammation, are rarely susceptible of being absorbed; the opening of them, therefore, is almost inevitable. Chronic abscesses, which are generally provided with thick cysts, also admit not of removal by this practice; it being generally requisite to excite a new action in their parietes,

which may modify their texture, and render them susceptible of contracting the adhesions requisite to their obliteration. The majority of purulent collections which are removed by absorption, is such as form rapidly, without much previous inflammation, and in debilitated habits, or in those weakened by pre-existing disease. In persons of this description, the excitement or irritation of the kidneys, or of the mucous surfaces, will often overcome the irritation existing in the seat of abscess, and consequently promote the absorption of the pus it contains; at the same time that the fluid abundantly secreted by the parts artificially excited will assume, in consequence of the state of the patient, a puriform character. (DUPUYTREN.) But, in the majority of instances of this kind, it is necessary that the artificial irritation or excitement shall be greater than that previously existing in the seat of abscess, and that the organs or parts in which it is induced be in a sound state; otherwise the revulsion cannot be either successfully or safely practised. However we may explain the mode of action of revulsants on abscesses of this kind, there can be no doubt that it is almost entirely in them, and particularly when they are seated in lymphatic glands, that we can hope successfully to employ this plan of cure.

58. When the evacuations procured from the first passages, and from the kidneys and skin, have no effect upon the tumours, and particularly if the stomach and bowels seem to support their action with difficulty, they must be abandoned, and recourse be had chiefly to the more direct means of cure. The local excitants, as iodine, the sulphureous *douches*, frictions with mercurial, camphorated, and terebinthinated liniments, and the repeated application of blisters for a short time, are only suited to the chronic kinds of abscess, where little or no inflammatory action exists. But these remedies should be watched, lest they increase the heat and inflammatory action of the external or superficial part of the tumour, and thus occasion their external opening.

59. In the majority of abscesses, it is requisite to keep three facts in recollection: 1st, that the inflammatory action in their parietes does not cease on the formation of the purulent collection; 2d, that an abscess is generally a complication of this inflammation, and of the retention of purulent matter in the inflamed parts which formed it, the inflammatory action being still present, although in a somewhat modified state and grade, and still continuing to form this matter; and, 3d, that the existence of pus does not necessarily or materially change the nature of the action which produced it. The therapeutical indications to which these facts necessarily lead are important, particularly as they show, what, indeed, has been proved by experience, that antiphlogistic remedies, especially those of local application, should not be laid aside with the supervention of suppuration. In the majority of cases, and particularly when increased heat of the part still continues, this class of local remedies should be employed with an energy in proportion to the activity of the local symptoms. As long as pain, redness, heat, and tension remain around the abscess, so long should leeches, or other modes of capillary depletion, directed to its vicinity, be had recourse to, particularly if the state of the patient offers no urgent indications against the practice.

Emollient and astringent applications should also be constantly employed. These will generally reduce the inflammation of the surrounding tissue, favour the resolution of the parts not yet suppurated. limit the quantity of the morbid secretion, and favour the maturation of the abscess, so that it may be opened with the best hopes of success. In some cases, the use of these antiphlogistic measures will give rise to the absorption of the purulent matter, even after this had been attempted to no purpose by means of revulsants.

60. It should be recollected that the surfaces of abscesses are the constant seat of two kinds of action; one of exhalation or secretion, the other of absorption; and that whatever excites or irritates them increases the former, and whatever soothes or diminishes this irritation lessens it, and favours the latter action. This consideration should lead us strenuously to adopt a continued antiphlogistic and soothing treatment of the affected part, until the thinning of the skin at the most prominent part of the tumour indicates the necessity of opening it.

61. In symptomatic abscesses, the treatment should chiefly be directed to the primary seat of disease; for as long as the mischief continues or advances there, the purulent collection increases, and diminishes as it subsides. Thus, the abscesses that point near the anus or crural arch, in consequence of disease of the vertebræ, will sometimes disappear after the use of active means directed to the original malady, and judiciously adapted to the state of the patient.

62. Consecutive and spreading abscesses require a very different management from that now pointed out. These generally occur in persons of an unhealthy habit of body, or who have been weakened by acute disease; or they are the result of an adynamic or ataxic and spreading inflammation occasioned by a specific or poisonous agent; and they are not unfrequently the consequence of the inflammation of veins, or of the presence of morbid secretions or purulent matter absorbed into the circulation (§§ 25—28.), or of the transfer of irritation from a distant part. But from whatever cause they may proceed,—and they may, and occasionally do, proceed from either of those sources,—deficient constitutional energy, and vital resistance to the influence of the exciting cause, with a marked disposition of the structures to be invaded by it, and to participate in the morbid action it excites, are their constant concomitants; requiring the energetic use of those means which are the best calculated to rouse the powers of the frame, to restore the deficient tone of the capillary vessels, and to thus enable them to form coagulable lymph, by which the spread of the local mischief may be limited. Instead, therefore, of having recourse to antiphlogistic remedies, the state of local action, and of constitutional power, requires a tonic, stimulating, and restorative treatment; conjoined with the means best calculated to promote the functions of all the abdominal viscera, so that morbid matters may be eliminated from the circulating current, and healthy nutritious elements conveyed into it; and with a pure air to perfect the changes which it undergoes during respiration, and which are requisite to the continuance of the functions of life. The treatment necessary in such cases is fully detailed in the articles on INFLAMMATION of

VEINS, on SPREADING INFLAMMATION of the CELLULAR TISSUE, and on the treatment of ANIMAL POISONS.

63. 2d, *Of opening abscesses.*—When we fail in procuring the absorption of the puriform matter, its artificial discharge will, sooner or later, be required, when this can be accomplished. Certain abscesses require a more immediate performance of this operation than others, and more particularly the following:—1st, Abscesses proceeding from the escape, into the substance of any organ or part, of irritating secretions or excremental matters, as the urine, or faecal substances. 2d, Abscesses preceded by very acute inflammatory action, and occurring in cellular or adipose structures, 2d, the margin of the anus, the sides of the neck, or the groins. 3d, Purulent collections deeply seated, or confined under fasciæ or aponeuroses. 4th, Abscesses formed in the parietes of the splanchnic cavities, in order to prevent the chance of their breaking internally. 5th, Abscesses formed in parts through which large nerves and blood vessels pass, and on which the purulent matter occasions a painful and injurious pressure; as abscesses in the neck, and underneath the sterno-mastoid muscle, at the top and inside of the thighs and arms, &c. 6th, Abscesses which embarrass the respiratory organs, and which press upon the larynx, pharynx, or trachea, or which endanger the integrity of those parts.

64. In all these the strict antiphlogistic treatment will be requisite, unless they are of the diffusive or consecutive kinds, with emollient applications, in order to limit the extent of the inflamed parts, to diminish their size, and to hasten their maturation; and in many cases this mode of treatment must be continued for a considerable time after the discharge of the matter, in order to limit or prevent its re-accumulation, and to promote the collapse and diminution of the parietes of the abscess. The cases where it will be frequently necessary to retard the period of discharging the purulent collection, are chiefly those in which it is formed in the internal viscera, as the liver, spleen, kidneys, lungs, &c.; respecting which I have treated fully under their appropriate heads.

65. Chronic abscesses should be opened as soon as it is shown that their absorption cannot be accomplished; or when they augment in bulk under the discutient and derivative treatment. Symptomatic abscesses also require to be opened, when we find that the means which we have directed to the original seat of disease fail of limiting their extension, or lessening their bulk. Consecutive abscesses require to have their contents immediately discharged, when their situation admits of this being done; for the morbid state of the matter they sometimes contain, and the weak vital resistance opposed by the surrounding parts and by the constitution, favours the contamination of the adjoining structures, and, indeed, of the whole frame. But this intention can seldom be fulfilled, owing to the seat of the purulent collection; and, when it is put in practice, it should be followed by as complete an exclusion of the atmospheric air as possible.

66. It does not come within the scope of this work to notice, at this place, the different modes of opening abscesses, and the treatment with which the operation should be accompanied and

followed. This necessarily differs in every case; but that part of it which belongs to my province is stated at the place where abscesses in the different viscera are discussed, and the means which may be employed to procure the obliteration of their cavities, the *second* intention of cure, are noticed, with reference to abscess of each of the important viscera and structures in which it is liable to form.

ABSORPTION. SYN. *Absorptio*, Lat. *Absorption*, Fr. *Die Einsaugung*, Ger. *Assorbimento*, Ital.

CLASSIF. GENERAL PATHOLOGY and THERAPEUTICS.

This is one of the most important functions in the system, and one of the most frequent channels through which disease is caused, perpetuated, or removed. As to each of these relations it requires a brief notice.

1. OF ABSORPTION IN RELATION TO THE CAUSATION, PERPETUATION, AND THE REMOVAL OF DISEASE. — The importance of entertaining accurate ideas as to the channels through which noxious agents affect the system, must be manifest. Without them, many of our pathological doctrines must be erroneous, and the therapeutic indications founded on them worse than useless: on the other hand, just views as to the nature and extent of the causes which operate through this medium, give rise to the most important inductions, — the chain of morbid causation is traced without interruption, the nature of pathological conditions is more accurately observed, and ultimate effects are recognised in due connection with remote causes. The practical advantages which accrue are great: prophylactic measures are based on sound principles; remedial agents are directed with precision; and the physician prescribes in a spirit of rational induction, instead of blind empiricism.

2. The agents which affect the system injuriously through the medium of absorption consist, *first*, of those which are external and foreign to the body, and act upon it only occasionally, or under certain circumstances; and, *secondly*, of those which are generated in the body itself, and, when carried by means of absorption into the current of circulation, produce very important effects. The former rank among the primary causes of disease; the latter are themselves the result of disease, but become important secondary causes, perpetuating and generally increasing its

severity. The *first* class invade the system on the mucous and cutaneous surfaces, — the skin, the lungs, the alimentary canal, &c.: the *second* class form in the parenchyma or texture of organs and parts, or are generated on secreting surfaces, whence they are absorbed into the circulation. On each of these I shall offer a few remarks.

3. 1st, *Of absorption on the skin in relation to the production and removal of disease.* — *a.* That disease frequently proceeds in this way is evinced by certain contagious and chronic affections of the skin itself: that it is possible to produce various derangements, by applying to it several active agents, which affect this surface no further than in being absorbed from it, may be proved by direct experiment. But it is chiefly when the skin is deprived of a portion of its cuticle, however minute, that we perceive affections produced through the medium of cutaneous absorption. Several eruptive and contagious diseases are familiar examples of this; and the majority of deleterious agents produce a most decided effect when applied to the skin thus exposed.

4. *b.* The same channels through which disease invades the system, are often the most suitable through which to counteract or remove it. This is shown by the treatment of syphilis; by the use of baths, lotions, fumigations, and inunctions in cutaneous and visceral affections: and by the employment of various remedies to the skin, which are partially absorbed from it into the system. When the skin is deprived of a portion of its cuticle, it absorbs rapidly many of the most active agents employed in medicine; and it is thus rendered one of the most eligible situations to which we can direct our plan of cure. Thus, when the stomach will not retain the sulphate of quinine, it may be efficaciously administered to the denuded cuticle; or when we wish to produce an anodyne effect upon the system, or to assuage violent pain, the preparations of morphia, as the acetate, may be applied in this way. And in various diseases, when the function of deglutition is lost, or the mouth cannot be opened, certain active remedies may be thus administered; more especially those which produce their effects after having been absorbed into the circulation. Even purgatives, as the croton oil, and elaterium, some preparations of iodine, strychnia, prussic acid, tartar emetic, &c., if judiciously employed in this way, will be often productive of advantage, and are not infrequently required to be thus prescribed.

5. 2d, *Of absorption from the lungs in relation to the causation and removal of disease.* — *a.* There are very few, if indeed any, of the numerous maladies which are usually denominated infectious, that are not caused through the medium of the lungs. And, though the greater proportion of them are most probably induced from the morbid impression which their exciting causes make upon the nerves supplying this organ, yet several of them are also, more or less, occasioned by the absorption of the cause itself into the circulation, and by its influence upon the blood, and the nervous and vascular systems. Probably, also, certain other causes of disease, of no mean importance, particularly marsh miasmata, and noxious animal exhalations, act directly upon the organic nerves of the lungs, and on the blood itself, through the medium of absorption. We

have reason, moreover, not only to infer that the more material causes of disease are absorbed from the surface of the lungs, when inhaled into them with the atmosphere, in the moisture of which they are dissolved, or otherwise combined; but, also, that the foreign gases, which sometimes mix with the air, act in some measure through the same channel.

6. The organisation of the respiratory surfaces, the nature of the circulating functions on these surfaces, and the more immediate relation subsisting between the air in contact with, and the blood circulating in, them, will readily explain the rapidity with which foreign matters floating in the atmosphere are frequently conveyed into the circulation. Besides, we have strong reasons to infer that several of the gases, and of the soluble substances which float in the air, are carried directly into the blood from the surface of the lungs, without passing along absorbent vessels. The experiments of Professor MAYER, and of Drs. LAWRENCE and COATES, as well as those of MM. SEGALAS, FODERA, &c., fully confirm this inference; whilst those performed by MM. MAGENDIE, SEILER, FICINUS, TIEDEMANN, GMELIN, and several others, show, that even in the alimentary canal, and especially when capillary vessels are divided in any of our tissues, the function of absorption is not confined to lacteal or lymphatic vessels, but is frequently extended to the venous capillaries, which, in respect of certain substances particularly, chiefly perform this function. Hence I may conclude that foreign substances dissolved in or combined with, the moisture of the air, or mixed with this fluid, may, when inspired, be carried from the surface of the lungs into the blood, independently of the absorbent vessels; although, doubtless, these vessels perform their appropriate functions in this as in other parts of the body.

7. *b.* The rapidity of absorption in the lungs, and the ready access to the blood which foreign matters find through them, are sufficient to vindicate their importance as channels through which to convey our means of cure, not only in those maladies to which they are liable, but also in a number of diseases affecting the whole frame, or particular parts of it. General suggestions on this subject are all that can be advanced in this place: the particular recommendations for its use are given in their appropriate places. Those gaseous bodies which possess active medicinal powers; all those remedies which are more or less volatile, or are soluble in aqueous vapour; and many medical substances which may be rendered volatile or soluble in water, when combined with other bodies that do not destroy altogether their remedial powers, may be prescribed advantageously through the medium of the lungs. Chlorine, the nitrous oxide, dilute oxygen gas; the vapour of iodine, or the sulphuret of iodine; the vapour of turpentine, camphor, of the common, the aromatic, or the pyroligneous vinegars; tar vapour; the chlorides or chlorurets of lime or of soda; aqueous vapour holding the active principles of opium, henbane, hemlock, belladonna, digitalis, colchicum, &c., in solution; the volatile principles of various salts, the aroma of a number of vegetable bodies,—all exert powerful effects upon the system when administered in this way.

8. *c.* Through this channel a number of fevers, especially those which are characterised by great

depression of the powers of life, or which rapidly pass into this state; various chronic affections of the lungs themselves, which are unattended by acute inflammation, but consist chiefly of a morbid state of the respiratory nerves, and are accompanied with spasm, and a morbidly increased secretion; the different kinds and forms of asphyxy; the diseases which threaten life by interrupting the respiratory functions; and various maladies in which the blood is vitiated, and where it becomes important to act in a direct and decided manner on this fluid, and on the circulating organs generally, may be successfully combated.

9. *d.* The knowledge that we thus acquire respecting the channels, through which the causes of many diseases invade the system, and the remedies for removing them may be efficaciously administered, furnishes us with important indications as to the employment of *prophylactic measures*, and rational plans of regimen and hygiene. Miasmatic or contagious fevers furnish us with numerous opportunities of proving the justness of these views. Observation shows us that the causes of this class of disease act upon the system chiefly from their presence in the air we breathe: it further enables us to decide that these causes invade the system chiefly through one of two, or perhaps by both routes: viz. by the nerves supplying the respiratory organs, or by the partial absorption of the causes themselves, from the pulmonary mucous surface, into the circulation. From the same source, or from the collateral evidence of experiment, we know that foreign substances do not so readily enter the circulation, when its functions proceed with energy, and the vital resistance is perfect, as when they act feebly and imperfectly; and that the depressing causes of disease have less power over the nervous influence of the respiratory organs, and of the system in general, when the vital actions which take place in the lungs are performed with due activity. The same sources of observation make us acquainted with the important facts that the dilution of the atmosphere, which contains the causes of febrile diseases floating in it by free ventilation; that the destruction, or neutralisation, or counteraction, of these causes, by the evaporation of certain disinfectant and stimulating agents; and that a due energy of all the vital and secreting functions, with an equable state of the mental powers and manifestations, and with a steady confidence, are the most successful means of preventing the attack and diffusion of those maladies.

10. By combining these facts as to the source, mode of operation, and methods of counteraction, of the chief causes of a most important class of maladies, and by directing the measures they suggest, as far as may be, according to the peculiarities of individual cases and diseases, we are thereby enabled to furnish persons, and even whole communities, with instructions and means calculated either to counteract or to lessen the dangers to which they are exposed.

11. 3d, *Of absorption from the alimentary canal, in connection with the causation of disease.*—*a.* It may be received as a pathological axiom, that the rapidity and extent with which deleterious matters are absorbed from the digestive mucous surfaces, as well, indeed, as from the respiratory, and other organs of the body, are nearly in pro-

portion to the depression of the nervous energies and vital resistance of the system. The truth of this is evinced in respect not only of the actions proceeding on the mucous surfaces, but also of those taking place in the different organs and structures. It is necessary to allude here to the numerous agents which cause, counteract, or remove disease, by their being absorbed from the alimentary canal. Whilst many agents produce their effects chiefly by modifying the states of the nerves and mucous tissue of this canal, others act principally from being absorbed, either by the lacteals, or by the venous radicles, and carried into the circulation; and a still more numerous class seem to operate through both channels, impressing immediately the nerves and tissues to which they are applied, and subsequently being absorbed into the blood, where they produce important effects not only upon this fluid, and on the vascular system, but also upon the functions of various secreting organs, especially those by which they are eliminated from the body.

12. A very large proportion, therefore, of the ingesta, whether alimentary, medicinal, or poisonous, thus acting upon the system chiefly through the medium of absorption, the importance of directing a considerable portion of attention to this function in our pathological investigations, as well as in the appropriation of medicinal means, must be apparent. Besides these more obvious relations of the subject, there are others which have been either imperfectly investigated or entirely overlooked. To these I can merely allude: but amongst the most interesting are the absorption of unwholesome and imperfectly digested chyle from the intestinal surface; the absorption of a portion of the vitiated secretions which occasionally accumulate in the alimentary tube, particularly in the cæcum and cells of the colon; the absorption of some part of the faecal matters, when they are long retained in the above situation, as evinced by the sensible qualities of the perspiration, foul state of the skin, &c., or of the obstructed and accumulated urinary secretion, as proved by similar phenomena; the passage of bile into the circulation, when it has been retained in the liver, the biliary ducts, or gall-bladder, from torpor or obstruction of these parts, or when it is secreted in large quantity, and does not readily pass off with the egesta. All these are very fruitful sources of disease; and, although generally connected with some degree of pre-existing disorder, or of torpid function, they are often the chief aggravating causes of many of the maladies we are called upon to treat, from the constitutional and visceral disturbance they occasion and perpetuate.

13. There are few disorders which implicate the digestive and chylopoietic organs, and very few febrile diseases, which do not, at some period of their course, evince signs of the absorption into the circulation of a portion of the morbid secretions or faecal fluids retained in the alimentary canal, when due evacuations are not practised. Therefore, besides the other effects produced by medicines of this class, evacuation of these secretions and faecal matters from the prima via is one of the best offices they perform.

14. *b.* It is unnecessary to do more than to allude to the advantages that accrue to the scientific practitioner from some knowledge,—although, in the present state of medicine, necessa-

rily imperfect,—of the remedies which act by being absorbed, either altogether, or in part, from the alimentary canal. Most of those substances which are found by experience the most efficacious in promoting the actions of the different secreting viscera, and in producing a marked and permanent change of the general state and functions of the economy, operate after having been absorbed into the circulating current, and conveyed through this channel to vital and secreting organs; and, although, during the healthy performance of the secreting functions, or whilst the vital energies are not far reduced, these substances seldom accumulate in the blood so as to be detected in it by chemical analysis owing to the balance which is preserved between the rapidity of absorption and the activity of elimination, yet their passage through it is proved by the fact, frequently observed in regard of all of them, of their being found in the secretions of the eliminating or depuratory organs. This fact was established by experiments performed by myself,—some of them as far back as 1819,—and published in several periodicals in 1821 and 1822.

15. 4th. *Of absorption from structures during disease.*—*a.* Adipose and other tissues, undergo waste and absorption; the absorbed elements forming combinations during circulation and excretion, thereby often perpetuating or aggravating disease.—*b.* When morbid secretions are generated, or accumulated in any organ or texture, or when any part is changed in such a manner as to secrete a matter different from the healthy constituents and fluids of the body, the matter formed is, after a while, absorbed into the circulation, and contaminates, in a more or less marked manner, according to its nature, the fluids and soft solids, and thereby at last destroys life. Illustrations of this are furnished us in the pathological history of internal and deep-seated abscesses; in some morbid states of the uterus; and in malignant diseases. The celerity with which the absorption of the morbid matter and the contamination of the frame proceed, is generally according to the principle already recognised (§9.),—in proportion to the diminution of the vital energy and resistance of the constitutional powers.

16. *c.* The commencement of the contamination can scarcely be determined by an appreciation of symptoms; but the experienced observer will readily recognise, in the colour of the surface of the body; in the state of the heart's action, and of all the circulating functions, as well as in the blood itself; in the failure of the energies of life; in the morbid condition of the nervous functions and of the powers of the stomach, and indeed of the whole digestive canal, sufficient proofs of the early, as well as of the advanced progress of disease, arising from the absorption of morbid matters from the primary seat of morbid action, and the consequent vitiation of the circulating fluids, of the soft solids, and of the secretions and excretions of the body. (See *Art. Blood.*)

17. *d.* In many of the more chronic diseases which either commence with or terminate in the malignant state, this contamination is frequently first evinced by the tumefaction and pain of adjoining lymphatic glands, owing to the irritation produced by the morbid fluid conveyed into them: the inflammation or obstruction thus produced in them becoming an obstacle to the rapid transit of the

morbid matters from the original seat of disease into the circulation. But in many cases this is an insufficient barrier; and in others, these matters seem to pass onwards, either without circulating through lymphatic glands, or without occasioning irritation, obstruction, or inflammation in them; or are almost directly conveyed into the venous circulation. Whatever may be the channel of conveyance, there can be no doubt of the fact—the practical importance of which is very great—that the rapidity of the absorption of morbid matters, and extent of their hurtful effects on the constitution, are in proportion to the depression of the vital energies of the frame,—this depression being frequently the cause of their absorption, particularly in respect of puriform fluids; or at least the circumstance which more especially favours its occurrence, and the rapidity of its progress.

ABSTINENCE. *Its Morbid Effects.* SYN. *Abstinentia*, Lat. *Astinenza*, Ital. *Die Enthaltung*, Ger. *Abstinence*, Fr. *Starvation from Hunger*.

CLASSIF. I. CLASS, V. ORDER (*Author, see Classification in the Preface*).

1. It does not come within the scope of this work to enter upon the consideration of the therapeutical relations of abstinence; but that the practitioner should be acquainted with the states of disease which it occasions, and with the best means of treating it, is extremely important; more especially as, when it is too rigidly enforced during the treatment of several diseases, it not infrequently gives rise to effects of a serious nature, which not infrequently have been mistaken for the spontaneous course of the malady.

2. I. OF THE MORBID EFFECTS OF ABSTINENCE. Abstinence has been long employed as a means of cure, and generally as a part of the antiphlogistic regimen, in a very great number of diseases, particularly in fevers and inflammatory affections. Very great difference, however, exists both among writers and practitioners as to the extent to which it should be carried, and the maladies in which it ought to be prescribed. As to its applicability to the class of diseases now noticed, there is no doubt: but in disorders of debility, or of irritation merely, particularly those which occasionally simulate chronic inflammation, and in various nervous affections, it is extremely injurious; and I believe that it has been carried to a hurtful extent in many of the affections, particularly by BROUSSAIS and his followers, as indeed has been recently well shown by MM. PIGNY and BARRAS. A case of this description, which had been long under the care of M. BROUSSAIS, very lately came before me, with many of the morbid effects of this practice, which had been carried to a hurtful extent. There can be no doubt, however, that it is extremely beneficial, when carefully watched and regulated, in many of the diseases of the stomach and its associated viscera; but the fact is equally incontrovertible, that it will often produce effects very nearly resembling those for which it has been prescribed. The importance, therefore, of keeping these effects in recollection,

when treating several diseases, particularly those of irritation and debility, must be apparent.

3. In appreciating the usual effects of abstinence it is extremely requisite to be aware of two things: 1st, That the effects vary with the state of the patient at the time that abstinence is endured; 2d, that they differ materially according to the suddenness with which it is entered upon, the extent to which it is carried, and the circumstances with which it is associated. By very corpulent and plethoric persons, abstinence is generally borne well for a long period, and by those labouring under febrile or inflammatory excitement; and it is, in them, one of the most necessary means to diminish the one and lower the other. In these, particularly the latter, total abstinence may be endured for many days; whilst, if carried to the same extent in healthy persons, its effects would be fatal, or nearly so. Abstinence, also, is longer endured by persons of the middle or matured epochs of life, than by those of an early age.

4. That the absolute or sudden deprivation of food should be productive of more rapidly serious effects is very obvious; but it is not so well known that there are circumstances which modify the effects of the less absolute states of abstinence, and which, when thus combined, give rise to very important and dangerous diseases. In order to place the subject more clearly before the reader, I will first notice the effects of abstinence simply, and unassociated with other causes of disease; and next, the morbid conditions, which its association with certain influential agents usually occasion.

5. 1st. *The morbid effects of simple abstinence.*—Keeping in recollection the modifications depending upon the extent to which deprivation of nourishment is carried, and the age and state of the person at the time of its adoption, I may briefly describe the morbid effects of abstinence as follows.—Paleness and languor of the countenance; muscular debility and emaciation; a weak and small pulse; thirst; at first quickness of intellect, constipation, and flaccidity of the muscles. To these succeed increased frequency of pulse, palpitations, alternating with leipothymia, or even full syncope; headach or delirium; flashes of light before the eyes; tinnitus aurium; slight amaurosis; parched state of the throat, and thirst; pains in the stomach; great wakefulness, followed by delirium, sometimes mild, but in other cases furious, or at first mild or muttering, and afterwards strong or furious; sinking of the animal heat, or alternate coldness and burning in parts of the body; and lastly, morbid sensibility of the organs of sense and surface of the body, and greatly depressed temperature, followed by insensibility, stupor, or coma, terminating in death.

6. It is obvious that the severity and duration of these symptoms will vary in different cases, according to circumstances peculiar to each. But it is not so well known that they will be actually produced by pursuing a too rigid abstinence in the treatment of various diseases, and particularly when the nature of the disease is mistaken: as when the irritative symptoms frequently attendant upon diseases of debility, or on nervous affections, are viewed as resulting from inflammation. Many cases have occurred to me in the course of practice, where the antiphlogistic regimen, which had been too rigidly pursued, was itself the cause of the very symptoms which it was

employed to remove. Of these symptoms, the affection of the head and delirium are the most remarkable, and the most readily mistaken for an actual disease requiring abstinence for its removal. A case of this description lately occurred to me. A professional man was seized with fever, for which a too rigid abstinence was enforced, not only during its continuance, but also during convalescence. Delirium had been present at the height of the fever, and recurred when convalescent. A physician of eminence in maniacal cases was called to him, and recommended him to be removed to a private asylum. Before this was carried into effect, I was requested to see him. A different treatment and regimen, with a gradual increase of nourishment, were adopted, and he was well in a few days, and within a fortnight returned to his professional avocations.

7. *The morbid appearances* observed after fatal cases of deprivation of food possess some interest. The most remarkable are the emaciation and absorption of every particle of fatty matter; the paleness, flabbiness, softening, and emaciation of the voluntary muscles, and of the substance of the heart; an exsanguined and pale state of the viscera; slight atrophy of the liver and spleen; diminished size of the stomach and colon; and particularly the increased vascularity of the brain, and sometimes of the membranes also, compared with the other viscera. It would seem that a very large proportion of the blood continues, as in many cases of great vascular depletion, to be sent to the brain to the very last. This is obviously owing to the pressure of the air on all parts of the body, from which the encephalon is guarded by its unyielding case. In addition, also, to the vascularity of this part, a limpid serous effusion between the membranes, or in the ventricles, is sometimes met with.

8. 2d, *Of the morbid effects of abstinence when it is associated with other hurtful agents.*—These effects are occasionally presented to medical men under a variety of circumstances, and from a varied combination of causes; but in the great majority of instances they result from deficiency of food merely, rather than from a rigid abstinence, conjoined with the depressing influence of cold or insufficient clothing, great or continued exertion, or with a moist and unwholesome atmosphere. Thus we find the association of these causes, particularly insufficient or unwholesome food, laborious exertion, mental depression, a moist, cold, or unwholesome atmosphere or locality, not infrequently give rise to purpura hæmorrhagica, scurvy, scorbutic dysentery or diarrhœa, low or typhoid fevers, affections of the brain and nervous system, emaciation, with chronic ulcerations, &c.—effects which have received a particular notice in their respective articles.

9. The best illustration of the effects of this association of other agents with a continued deficiency of food is furnished by the diseases which appeared a few years ago in the Milbank Penitentiary. The prisoners confined in this prison were suddenly put upon a diet from which animal food was nearly altogether excluded, excepting in as far as it entered into the composition of a weak soup. They were at the same time subjected to a low grade of temperature, to considerable exertion, and confined within the walls of a prison situate in the midst of a marsh which is below

the level of the adjoining river. The consequences were, first, the loss of colour, of flesh and strength; subsequently, diarrhœa, dysentery, scorbutic dysentery, scurvy; and, lastly, low ataxic or adynamic fevers, or headache, vertigo, convulsions, delirium or mania, apoplexy, &c. The smallest loss of blood produced syncope or leipthymia, and fatal results. Yet, in the great majority of the fatal cases, independently of the lesions observed in the mucous surface of the digestive tube, or in other situations, increased vascularity of the brain and its meninges, frequently with effusion of fluid in the ventricles or between the membranes, was found upon examination after death.

10. II. The TREATMENT of the morbid effects of abstinence is very obvious, yet considerable care is necessary to its successful issue in very urgent cases. Nourishment should be administered cautiously, in a very small quantity at a time at first, but frequently. It ought to be bland and farinaceous: animal food may be entered upon subsequently, and the quantity gradually increased. The animal warmth should be promoted, at the same time, by the usual external means—by frictions and warm applications; and the bowels assisted by the occasional use of bland enemata. Soups may be allowed early in the treatment, but in a small quantity at a time. Milk is often prejudicial, unless diluted and made into gruel with some of the farinaceous articles of food. Internal stimulants are seldom required, unless when symptoms of cerebral or nervous irritation exist, when they may be given; particularly the preparations of ammonia, the æthers, camphor, vegetable bitters and tonics, at first in very moderate doses, in conjunction with small quantities of an anodyne, as the extract of hop, the extract of hyos-cyamus or of opium, the pægoric elixir; and by warmth, frictions, and stimulating applications to the cutaneous surface and lower extremities. These means will generally succeed in removing the effects of simple abstinence whilst they admit of removal. The treatment of the effects resulting from the conjunction of other causes with the one now discussed, is considered under their respective heads.

CLASSIF. 3. Class, Diseases of the Sanguineous Function; 2. Order, Inflammation (Good); 7. Order, Tubercles (*Willan* and *Bateman*). IV. CLASS, IV. ORDER (Author, see the Classification).

1. DEFIN. Hard, inflamed, tubercular tumours, suppurating very slowly, occurring chiefly in the face; sometimes, also, on the neck and shoulders.

2. 1. DESCRIPTION. One or more, sometimes a number, of these tubercles appear, generally in

succession, in the face, and sometimes on the neck, shoulders, and breast, but never lower; remain permanent for a considerable time; and suppurate slowly and imperfectly, leaving a dark or livid mark, which gradually disappears. They occur chiefly in persons of the sanguine temperament; commencing at the period of puberty, and generally disappearing after thirty or thirty-five. They are common to both sexes, but are most frequent and numerous in the male sex.

3. This is one of the most constant and unvarying in its characters of any of the affections of the skin; but writers upon this class of diseases differ widely in respect both of its particular character and seat. WILLAN, PLECK, BATEMAN, and THOMSON consider it a tubercular affection; whilst ALBERT, BIETT, and RAYER view it as pustular. I believe, however, that both opinions are in some respects correct; and that in certain forms or states of acne the tubercular change is predominant, little or no suppuration taking place, but a state of slow inflammation giving rise to a continued exfoliation of the cuticle, or formation of thin scabs on their apices; and thus they slowly disappear; whilst in others the pustular character is very distinct, but always preceded by the characteristic tubercular hardness. This affection may be viewed, therefore, as forming an intermediate link between the tubercular and pustular eruptions.

4. In respect of the particular tissue in which this disease is seated, some difference of opinion also exists. The greater number of writers on the pathology have considered this disease to be seated in the proper structure of the cutis vera; many of them admitting, at the same time, an affection of the sebaceous follicles very nearly resembling it. Mr. PLUMBE, however, attributes it entirely to obstruction and chronic inflammation of these follicles. I believe that this opinion is too restricted; and that, whilst one form of acne evidently depends upon this cause, others are essentially disease of the cutis vera.

5. Spec. i. ACNE SIMPLEX, *Simple Acne*. Syn. *Gutta Rosea Hereditaria*, Darwin. *Dartre Pustuleuse Miliare*, Alibert. *Ionthus varus simplex*, Good.

Simple acne affects most frequently young subjects at the period of puberty, and particularly females. They generally appear on the forehead, shoulders, and upper part of the thorax, and are liable to recur at the menstrual periods, especially in cases of dysmenorrhœa. Many of these vari do not proceed to suppuration, but slowly subside. They are very commonly developed in succession; commencing with small, hard, and inflamed tubercles, of the size of a pin's head. These continue to enlarge for three or four days, and the inflammation becomes more apparent. In seven or eight days they have reached their greatest size. They are then dark red, smooth, prominent, shining, hard, and slightly painful to the touch. After two or three days a small speck of matter appears on the apices of some of them; and when these break, a thin humour exudes from the tubercular induration, and dries on its surface, forming a thin scab, which adheres firmly; but, after a few days, is loosened at the edges, and falls off; the tubercular hardness and livid redness gradually subsiding, and disappearing after three or four weeks.

6. In some persons this eruption recurs frequently at short intervals, the vari being more or less numerous; in others it is more extensive, and never altogether disappears, although it is more troublesome at one time than another. When the vari are numerous, many of them undergo no suppuration; but the sebaceous glands are often excited, giving the skin a greasy appearance. In many of these cases, several of the vari assume the characters of the next species.

7. Spec. ii. ACNE INDURATA, *Stone-pock*.

The tubercles are larger, more indurated and permanent than the foregoing; and are apparently the consequence of a slower and more deep-seated inflammation. They often appear in considerable number, of a conical or oblong-conoidal form; some of them assuming a roseate hue, and tending to suppuration at their apices; others remaining in a hard, elevated state for a very long time, without any appearance of the suppurative process, or disposition towards it. In some cases, two or even more of them coalesce, and occasionally suppurate at their respective apices; but one only may undergo this change. As they continue they become more purple or livid, particularly when they have no tendency to suppurate. When they experience this process, the same process of scabbing and exfoliation, already described (§ 5.), is gone through; but it sometimes happens that when they experience any irritation they may suppurate a second time. As they very slowly subside, they leave a purple or livid discoloration, and, occasionally, a slight depression, which is long in wearing off, and which sometimes never altogether disappears.

8. This species of acne generally is most frequent and numerous along the rami of the lower jaw, on the temples, the nose, and cheeks; also on the back and neck. They are frequently accompanied by a greasy state of the skin, from an excited state of the cutaneous follicles; are commonly sore and tender to the touch; and, when numerous, are in every stage of progress, giving the surface a spotted and variegated appearance, — owing to the prominence and redness of some at their commencement, to the yellow points in those that are suppurating, to the scaly crusts covering those which have undergone this process, to the lividity of those that have exfoliated or are subsiding, and to the discoloured depressions which others have left after them.

9. The general health seldom suffers materially from either the simple or the indurated acne, excepting as far as regards some pre-existing and concomitant disorder of the digestive functions. If fever, or acute disease, attack persons affected with these eruptions, the vari generally disappear; but they frequently also re-appear upon its subsidence, becoming in some respects a critical eruption.

10. Spec. iii. ACNE ROSACEA, *Rosy-drop*. Syn. *Gutta Rosea*, Auct. var. *Gutta Rosea Hepatica*, Darwin. *Ionthus Corymbifer*, Good. *Dartre Pustuleuse Couperose*, Alibert. *Goutte Rose*, *Couperose Rougeurs*, Fr. *Kupferbandel*, *Roth-nase*, Ger. *Carbuncled Face*, Eng.

The first and second species, described above, might have been, with propriety, viewed as varieties of the same species; but this is a very distinct species from the preceding. It consists of

small, slowly suppurating tubercles, accompanied with a shining redness, and an irregular granulated appearance of the skin of the part affected. This species commonly appears first at the end of the nose, and afterwards spreads from both its sides to the cheeks, which it never altogether covers. At first it is not uniformly red; but is pale in the morning, and intensely red whenever the patient is excited or heated, and particularly after dinner, or drinking wine or spirits. After some time the texture of the cuticle is gradually thickened, and its surface granulated and variegated by the ramifications of cutaneous veins, and the suppurating of small, prominent vari, which successively arise in different parts of the nose and face.

11. This species of acne seldom appears before the age of forty, excepting in those addicted to the immoderate use of vinous or spirituous liquors, or who possess great hereditary predisposition to it. In advanced life, or in the worst of these cases, it sometimes spreads to the greater part of the face, even to the forehead and chin. The nose usually becomes very tumid, and of a fiery red colour, and sometimes is enlarged to an enormous size. The nostrils, in these cases, are generally distended, and their alæ often fissured and divided into lobes. In advanced age, this species of acne becomes more livid; and if any of the tubercles suppurate, they often ulcerate, and are indisposed to heal. In younger persons, who are attacked chiefly from hereditary disposition, it is often accompanied with irregular red patches on the face, which are often smooth, devoid of tubercles, and accompanied with occasional slight exfoliations of the cuticle. These patches are extended, or aggravated by intemperance in food or drink.

12. Spec. iv. ACNE PUNCTATA, *Maggot Pimple*.

Syn. *Crimones*, Auct. var. *Punctæ Mucosa*, Darwin. *Ionthus Varus punctatus*, Good. *Der Gries*, Ger. *Tannes*, Fr. *Grubs*, Eng.

This is, in my opinion, the only species of acne which is seated in the follicular glands; and, although often observed as the only form of eruption, it also is frequently found intermingled with the species already described, particularly the first and second. It consists of a number of black points, surrounded by a very slightly elevated border of cuticle, proceeding from concreted sebaceous matter accumulated in the glands and their ducts, whence it may be squeezed out in a vermicular form, the external extremity being dark from its exposure. In consequence of the accumulation and distension, these glands sometimes become inflamed, and give rise to small tubercles, with minute black points in the centre of their external surface. These tubercles suppurate partially, as the preceding, whilst others remain stationary for a considerable time, and several are distended without even being inflamed. They are not infrequently mixed with tubercles without the black punctæ, which are evidently owing to a similar obstruction, and to a more complete closure of the outlet of the ducts. In this species of acne the accumulated secretion may be squeezed out.

13. Spec. v. ACNE SYPHILITICA, *Venereal Acne*.

Syn. *Gutta Rosea Syphilitica*, Plenck. *Syphilitide Pustuleuse Milvaire*, Alibert.

Amongst the very numerous forms of cutaneous affection in which secondary syphilis may

manifest itself, this may be enumerated as one, although not a common one. PLENCK has given a very correct description of it. This species nearly resembles, in the size and form of the pustules, the acne rosea. It chiefly affects the forehead, face, neck, and upper part of the trunk. The vari are round and conical, with an inflamed, copper-coloured, tubercular base and areola. They suppurate slowly at their apices, where a yellowish-brown scab is formed; and leave a dirty, dark, and slightly depressed mark. They present a dark colour, and more permanent tubercles, on the nose, the adjoining parts of the cheeks, and forehead, than elsewhere; and are there observed in discoloured patches, in every stage of their growth. They are frequently found complicated with other eruptions, chiefly of a scaly character, on different parts of the body; are always a secondary venereal affection; and although sometimes unaccompanied with other syphilitic symptoms, are most commonly attended with ulcerations in the throat, with nodes, inflammation of the periosteum, and nocturnal pains.

14. 11. DIAGNOSIS. — *Acne* can be confounded only with *ecthyma*. The tubercular pustules of the former, however, are small, slowly developed, with an indolent and hardened base; whilst the pustules of *ecthyma* are large, superficial, unaccompanied with chronic induration, and forming thick scabs, more or less prominent, much less adherent, and such as never are formed in acne. The characters of *syphilitic acne*, the antecedent and accompanying symptoms (§ 13.), the colour and predominance of the eruption about the nose and commissures of the lips, the tendency of the vari to ulcerate, and the associated affection of the throat, and sometimes of the periosteum, sufficiently mark the nature of this species of the disease.

15. III. THE PROGNOSIS of acne regards merely the persistence of the eruption, and the inconvenience attendant on it. *Acne simplex* and *punctata* are often of comparatively short duration. The acne *indurata* is much more tedious; and in some constitutions will resist, even for many years, every mode of treatment, particularly if the causes in which it not infrequently originates be overlooked. *Acne rosacea* is seldom or ever cured, excepting by a strict attention to regimen.

16. IV. THE CAUSES of acne are extremely various. The species *simplex*, *indurata*, and *punctata* usually occur during youth, in the sanguine and bilious temperaments, and disappear about middle age. They are very generally connected with chronic affections of the stomach, bowels, and liver; with hæmorrhoids; in some, with a tendency to phthisis; and in females with painful and scanty menstruation. These species, as well as the acne *rosacea*, evidently arise in many cases from hereditary predisposition; and are most common in cold and moist climates,—probably owing to the use of ardent spirits. Excesses at table, cold indigestible articles of food, sedentary habits, fits of passion, anxieties of mind, and the depressing passions, cold drinks—particularly if taken when the body is overheated—the use of irritating cosmetics, and disorder of the digestive functions, are very common causes of these eruptions. I believe, however, that the simple, indurated, and punctated species of acne are

most frequently occasioned by uterine irritation, and excitement, or an imperfect performance of the uterine functions; by constipation; by torpid conditions of the liver; and by the injurious addiction to onanism.

17. V. TREATMENT.— In the treatment of these affections, our chief attention ought to be directed to their pathological relations and causes. These latter must be removed as far as may be done; and the former should both guide our indications, and direct our means of cure. The apprehensions entertained by the older writers, of producing internal disease by the sudden repulsion of the eruption, were founded on the results of observation, although explained by partially inaccurate or unsound pathological views. Affections of the stomach, bowels, chest, and head, have been thus induced, and been relieved upon a re-appearance of the eruption: but such consecutive diseases are more common after the repulsion of other eruptions. We should, however, as being both the safest and the most permanent method of cure, direct our remedies to the constitutional or internal relations, as well as to the external manifestations of disorder.

In the treatment of this, as well as many other diseases, the causes, the state of the habit and constitution of the patient, its morbid relations, and its duration, are severally to be kept in recollection.

18. 1st, *Treatment of acne simplex.*— In delicate constitutions, the chief attention should be directed to the state of the digestive functions. These should be promoted by gentle *aperients*, combined with *tonics*, and the functions of the skin promoted, by preserving a free transpiration on its surface. With this view, *sulphur* may be combined with *magnesia*, or with cream of tartar, and confected of senna, and taken in a sufficient dose, at bedtime, to procure a full evacuation in the morning, or any one of the formulæ (A.P. Nos. 82. 89. 98.) may be had recourse to. These may be occasionally changed for a powder with rhubarb, sulphur, and magnesia, or for the extract or decoction of taraxacum, with carbonate of soda or sulphate of potash. If the functions of the liver are torpid, the following may be taken for a few nights;—

No. 6. R. Pilul. Hydrarg. Chloridi Comp. ʒj.; Felis Tauri Inspiss. gr. xv.; Saponis Castil. gr. x.; Extr. Taraxaci ʒj. M. Fiat Pilulæ xviii., quarum capiat binas vel tres horâ somni.

After the bowels have been evacuated, and the secretions brought to a healthier state, the dilute *mineral acids*, either alone or with *bitter infusions*, may be taken through the day.

19. When the eruption occurs in young plethoric persons, and when it is in females attended with scanty and difficult menstruation, small *blood-lettings* may be practised; in the latter by the application of *leeches* to the superior and internal parts of the thighs. In more delicate females the functions of the lower bowels are to be promoted by the pilula aloës cum myrrha, combined either with pilula ferri composita, or with the extractum gentianæ. When the eruption is obviously connected with imperfect and painful menstruation, the use of the warm salt water *hip-bath*, or of the hip vapour bath, or warm salt water *pedituria*, after the application of a few leeches to the insides of the thighs, will be extremely serviceable. In such cases, the internal exhibition of the bi-

borate of soda, either in the form of pill or draught combined with camphor, the extractum taraxaci, or the extr. rutæ, or, as directed in Form. Nos. 93. 184. 209. 254. will be found of great advantage.

20. In addition to these internal remedies, which require to be varied according to different pathological relations of the eruption, external applications will be necessary; and when conjoined with the above treatment, or employed subsequently to it, no dread may be entertained of any injurious consequences from them. The ancients, particularly CELSUS, PLINY, AETIUS, PAULUS, ACTUARIUS, &c., recommended lotions and liniments with vinegar and honey; and these sometimes combined with turpentine, emulsion of bitter almonds, myrrh, alum, soap, Cimolian earth, the bruised roots of the lily, the cyclamen, narcissus, and the fruit of the wild vine; the most of them calculated to be advantageous in many states of the common forms of acne.

21. If the tubercles are much inflamed, and inclined to be pustular, mildly stimulating applications are most serviceable, as *dilute spirit*, or the *pyroligneous acetic acid*, or *liquor ammoniac acetatis*, with rose or elder-flower water. In the more indolent cases, or when the skin can bear an augmented stimulus, WILLAN and BATEMAN recommend from half a grain to a grain, or more, of the *bichloride of mercury*, in each ounce of the vehicle; or a drachm or more of the *liquor potassæ*, or of the *hydrochloric acid*, in six ounces: and THOMSON advises that the emulsion of bitter almonds, containing ten minims of *hydrocyanic acid* to each fluid ounce of the emulsion, should be the vehicle adopted. The solution of the *sulphuret of potassium*, in the proportion of a drachm to twelve or sixteen ounces of water, may also be employed; and, in the more obstinate cases, the *baths* directed in Form. No. 14—17. may be had recourse to. The solution of the *hydrochlorate of ammonia*, either alone or with the bichloride of mercury, is often serviceable.

22. The lotion from which I have derived the greatest advantage in practice, and which I have found the most generally applicable, is a solution of the *biborate of soda* in rose or elder-flower water, or in water which had been poured in the boiling state over sulphur, and allowed to infuse for ten or twelve hours. The borax may also be dissolved in equal quantities of elder-flower water and honey, and used as a lotion in the more chronic cases.

23. 2d, *Treatment of acne indurata.*— In young and plethoric subjects, or in females, when the eruption is accompanied with a scanty and painful menstruation, the treatment already pointed out (§ 19.) should be put in practice. When we suspect that sexual irritation or masturbation is connected with the causation of the eruption, early rising, mental occupation, the use of gentle cooling aperients, of soda combined with small doses of camphor, soda water, sulphur with soda or antimony, are the most serviceable internal remedies. After these, the mineral acids, the sulphureous mineral waters, and gentle vegetable tonics, will be useful. Where the eruption is dependent upon torpid function of the stomach, or liver, or bowels, mild alteratives, exhibited at bedtime, as the pills already prescribed (§ 18.), and gentle tonics through the day, will be required. In a most obstinate case, which some time ago

came before me in a lady, whom all the practitioners who had acquired a reputation in the treatment of cutaneous affections had attended, strict attention to the state of the digestive and uterine functions removed the eruption. The following electuary has sometimes been used by me in this and other obstinate cases.

No. 7. *R* Potassæ Bitart. in pulv. ʒj.; Bi-boratis Sodæ ʒjss.; Sulphuris Præcip. ʒss.; Confectious Sennæ et Syrup. Zingiberis aa ʒjss. *M.* Fiat Electuarium, cujus capiat Coch. unum minimum omni nocte.

At the same time a solution of two grains of the bi-chloride of mercury in four ounces of the compound tincture of cinchona was prescribed, and a teaspoonful of it directed to be taken twice daily, in half a glass of infusion of chamomile flowers. The lotion already recommended (§ 22.) was also employed. In cases similar to this, and, indeed, in all those accompanied with disorder of the digestive functions, cold or drastic purgatives ought to be avoided; and the bowels should be regulated with the pilula alöes cum myrrha, combined with a little blue pill, or with the pill prescribed above (§ 18.); or the ext. alöes purif. conjoined with the extr. gentianæ; or the electuary now directed. Advantage will also be obtained from a draught of infusion of cascarrilla, or of calumba. with carbonate of soda or potass, or the liquor potassæ, taken twice a day.

24. As to *external applications* in this form of acne, little need be added to what has been already stated. The lotions with the bi-chloride of mercury, or with the borax, are most to be depended upon, particularly when dissolved in an emulsion of bitter almonds, or in camphor mixture, with the addition of about twelve minims of the hydrocyanic acid to each ounce of the vehicle. In cases where the tubercles have at all suppurated, it will be advisable to open them with the point of a lancet before the lotion is used.

25. At the commencement of the eruption, mild emollient poultices and fomentations are useful; and afterwards, particularly in the more obstinate cases, M. BIETT, and after him MM. CAZENAÏVE and SCHEDEL, recommend the following ointments to be used, in order to promote the resolution of the tubercles:—

No. 8. *R* Protochloridi Hydrarg. et Ammonia * (Submur. Hydrarg. et Ammon.) ʒj.—ʒj.; Axungia ʒj. *M.* cc. Of this ointment I have had no experience; but the following I have employed with advantage in several chronic eruptions, and in two cases of this species of acne:—

No. 9. *R* Sulphureti Iodina gr. xii.—xxiv.; Axungia ʒj. *M.*

AMBROSE PARÉ and DARWIN considered that blistering successively small portions of the face was the most successful means of removing this very obstinate eruption. This practice has been employed at the hospital St. Louis, by M. BIETT, with great benefit. When the disease has disappeared, he has derived great advantage from a douche of cold sulphureous water in preventing a return of it.

26. 31. In treating the *punctated species* of acne, it will be frequently necessary to press out the accumulated and hardened matter from the follicles. The vapour bath, the warm sulphur bath, followed by frictions either with a coarse

towel or a flesh brush; and lotions such as have been already recommended, or a weak solution of pure potash, or of ox-gall, or of sulphuret of potassium, also followed by frictions, are particularly indicated in this species of acne.

27. *Internally*, the solution of the bi-carbonate of potash, or of chlorine, advised by UNDERWOOD and WILLAN, may likewise be employed. Sulphur, magnesia, soda, rhubarb, and the borate of soda, are also of much benefit. Dr. THOMSON states, that he has seen the skin completely cleared by the use of the following alkaline tonic for six weeks; at the same time regulating the bowels:—

No. 10. *R* Zinci Sulphatis gr. xxiv.; Liquoris Potassæ ʒxij. Solve. Sumanantur guttæ xxx. ex cyatho aquæ, bis quotidie.

It ought always to be observed, as a general principle, in this as well as in the other forms of acne, that attention to the secretions of the abdominal viscera, and to the general health, by promoting the digestive functions, will of itself, independently of external means, go far in promoting a cure; and that, without such intention, no cure will be permanent.

28. 4th, *The treatment of acne rosacea* is generally unpromising. It should always have a strict reference to the particular nature of the affection of the liver, or digestive canal, or both, with which this eruption is associated, and in many respects symptomatic. *A. rosacea* often precedes serious disease of the liver, more frequently co-exists with it, and most commonly indicates a congested and obstructed state of the viscus. To this organ, therefore, ought our remedies to be particularly directed. A moderate *blood-letting*; the application of *leeches* on the region of the liver; and, if the eruption occurs in females, and is attended with obstructed or scanty menstruation, leeches also to the upper part of the insides of the thighs, or bleeding from the feet, and stimulating pediluvia, or the hip-bath; the use of *mild mercurials*, or alternative and deobstruent medicines, such as the pills previously described (§ 18.); the blue pill, or the hydrargyrum cum creta with soda and taraxacum; Harrogate, Barège, and other sulphureous mineral waters; the decoction of dulcamara, liquor potassæ, and chlorine or sulphureous fumigating baths, are severally of advantage in some cases. But from none of these will any permanent benefit be derived, unless the regimen presently to be noticed is rigidly observed, and the pathological relations of the eruption appropriately treated.

29. *Blood-letting* in this, as well as the foregoing species of the eruption, was strongly insisted on by AMBROSE PARÉ; and certainly in the cases pointed out as requiring this practice should never be omitted; more particularly when accustomed discharges have disappeared, as the hæmorrhoidal flux and the menstrual evacuation. In this form of the disease, much advantage will sometimes be procured from the *nitro-hydrochloric acid* foot-bath; and from a lotion with these acids applied to the affected parts twice or thrice a day (see F. 4, 5.). This practice has received the sanction of MM. BIETT, CAZENAÏVE, and SCHEDEL. The advantages to be derived from the use of these acids as a lotion will be more certainly secured by applying a few leeches to the vicinity of the eruption, and afterwards a fomentation, which may be followed either by a spirit and alum or zinc lotion, or by

* Prepared by subliming equal quantities of the bi-chloride of mercury and hydrochlorate of ammonia.

the lotion with the bi-borate of soda (F. 334.). If these fail, the nitro-hydrochloric acid lotion may be employed. Stimulating and irritating applications ought to be avoided; and whilst the tone of the digestive organs and the secretions of the liver should receive the closest attention, drastic and cold purgatives are to be avoided.

30. 5th. The treatment of the *syphilitic* or specific form of acne must be directed as in other states of secondary venereal disease. At the same time, however, that the mercurial preparations are being exhibited, the external means which have been recommended may be employed, according to the particular form the acne may assume. The mercurial preparations should be combined with sarsaparilla or taraxacum, or both, and with small doses of antimony. The decoction of FELTZ, which chiefly consists of a combination of these remedies (see F. 588.), is much employed in these eruptions on the Continent, and may be taken to the extent of a pint and a half daily. When the tubercles remain long, the ointments formed with the iodides of mercury or sulphur (F. 774, 775.) may be employed twice daily, and assisted by douches of vapour.

31. The diet and regimen of persons affected with acne, particularly the *A. rosacea*, ought to be carefully restricted. In the *A. simplex*, *inurata*, and *punctata*, the diet should be light, nutritious, and easy of digestion. Cold, raw, and indigestible vegetables, particularly cucumbers and melons, and very cold fluids, should be avoided. Moderate and regular exercise in the open air, and early rising, as tending both to promote digestion and invigorate the frame, are always of service. In the *acne rosacea*, more will often depend upon regimen, than upon the medical treatment of the patient. The careful avoidance of all its exciting and concurrent causes, and of excesses of every description, both in eating and drinking; the adoption of a mild farinaceous diet, with a small portion only of light and nutritious animal food, and of toast-water or barley-water for drink; shunning mental excitement and depression, as well as heating and fatiguing exertions; gentle and regular exercise, and attention to the promotion of the secretions and functions of the abdominal viscera; are essentially requisite to the removal of this very obstinate and often unconquerable eruption.

ADHESIONS. SYN. *Adhésions*, *Adhærences*, Fr. *Die Anhänglichkeit*, Ger. *Congiunzioni*, *unioni*, *aderenza*, Ital.

CLASSIF.—MORBID STRUCTURE.—THERAPEUTICS.—Chiefly a result of some one of the *Inflammatory States*.—Sec INFLAMMATION.

1. *Adhesions* of opposite surfaces of tissues are amongst the most common organic lesions presented to our view in post mortem examinations. They may be congenital, arising either from an original disposition of parts, or from intra-uterine disease. As they are commonly brought before us in prac-

tice, they are generally one of the consequences of inflammatory action, affecting the adhering surfaces, or which had affected them previously; and occur in those parts which are in contact, or so nearly in contact, that the effusion of a common product of the inflammatory act becomes the medium of union.

2. It is requisite to all adhesions, that a fluid be thrown out from the inflamed surface, previously to the adhesion being commenced. This fluid varies somewhat in its characters with the state of inflammatory action; but it soon passes into a much more consistent condition, and thus becomes the medium of adhesion. In some places it is scarcely perceptible between those parts of opposite surfaces which are naturally very nearly or altogether in contact with each other, the agglutinating medium being there so remarkably thin; whilst those parts that are further separated in their natural state, have the interstices filled up by a copious exudation. The fluid exuded in thus variable quantities, has been denominated, in its first stages, or inorganised states, coagulable and coagulated lymph, albuminous exudation, coagulated albumen, &c. When first poured out from the inflamed surface, particularly of serous membranes, it consists of a lymph-like fluid, which soon becomes somewhat opaque, more solid, and assumes the appearance of a softly coagulated albumen,—its chemical properties very nearly approaching to those of pure albumen, containing a small proportion of the usual saline ingredients of the blood.

3. The longer this matter has been effused, and the longer adhesions, which it has occasioned, have endured, the more firm and more closely resembling cellular or cellulo-fibrous tissue do they become. This change in the state of the adhesions, according to their duration, is fully stated in the article on the morbid states of *serous membranes*. It may, however, be here premised, that the medium of adhesion, which is first fluid, and afterwards albuminous and nearly solid, soon becomes partially organised; blood-vessels shoot into it, and thus opposing surfaces become more or less firmly united, according to the degree of motion occurring between them, that may either prevent their firm adhesion, or disturb it after it has been already formed, and to the state of the fluid which becomes the medium of union. In some cases this fluid is secreted so copiously, and is so deficient in the albuminous constituent, the watery part being so predominant, that adhesions are formed only in different, or in numerous and irregular points, between which serum in various states is effused, separating the opposite and partially united surfaces, stretching the adhesions, breaking down some, and reducing others to cellular bands running between these surfaces through the effused fluid, which is in such cases usually very turbid, and abounds in flakes of albuminous matter. This appearance is not unusually observed in cases of adhesion of the pleura, pericardium, and occasionally of the peritoneum.

4. The concrescible fluid, as will appear in the sequel, which is formed between the surfaces of divided structures, originates in two distinct modes, generally assumes a firmer and more fibrous character in its advanced stages, and undergoes a more marked diminution of volume than is ob-

served in those adhesions which form on serous surfaces. From this it will be apparent that adhesions are formed by the medium, 1st, of a concrete inorganic albuminous matter; and 2d, of this matter, at a later period, in a more or less organised state, and presenting various appearances, according to the length of their duration, and the nature of the inflammatory disease which produced them. It will be also apparent, from the foregoing, that the adhesion of opposite surfaces is not in itself a specific disease, but the result of disease,—generally of inflammation in some one of its grades.

5. Adhesions, in respect of their ultimate tendencies, are either *reparative* or *morbid*.—M. CRUVEILHIER, who has divided them into two classes, according to this view, comprises under the former the adhesions between divided tissues and surfaces brought about by surgical aid; to which I may add those that take place around purulent formations, and prevent the extension or effusion of the collected matter into adjoining parts. Whilst the reparative class of adhesions are stated to form generally between divided structures and diseased surfaces, it should be kept in recollection that all the tissues do not admit of adhesion taking place immediately between their divided surfaces. Blood-vessels, nerves, muscular fibres, and tendons do not unite, after division. It is the minute vessels of the cellular tissue which surrounds them, and their individual fibres, that chiefly furnish the means of their adhesion. From these vessels, if protected from the atmospheric air, a coagulable lymph is thrown out; which gradually becomes vascular, organised, and in a few days cellulo-fibrous, and as firm as the parts which formed it. This newly produced substance is the medium by which the muscular fibres, or other structures which had been divided, are united; and this gradually becomes thinner and less apparent, and admits of the nearer approximation of the separated parts, until they at last seem continuous, although the existence of the medium of union may still be detected. This constitutes *primary* adhesion, the union by the “*first intention*” of surgeons.

6. When the division takes place between bones, this exudation forms the callus, into which ossific matter is deposited. Some pathologists believe that the concretescible lymph, thus furnished by the capillary vessels of the divided surfaces, particularly those of the cellular tissue, is the matrix, in which the peculiar structure, of which nerves or muscular fibres consist, is afterwards formed or deposited. But, if this were the case, the firm, and even fibrous, matter into which the medium of union is ultimately changed, would at last disappear, and these structures be actually continuous. This, however, never unequivocally occurs; for, although the uniting medium is reduced to a very thin, and scarcely perceptible, substance, yet it may be made apparent by maceration and careful dissection.

7. When air is admitted between the divided structures, or when primary adhesion fails of taking place, a different process obtains; minute granulae or carunculae form upon their surfaces, whence proceeds at first a fluid pus, subsequently a more concretescible fluid, which forms a sort of false membrane, and which, when the opposite surfaces are kept in a state of near approximation, be-

comes the medium of adhesion, unless the state of the system is such as not to admit of the formation of this concretescible fluid, and of the other steps of this restorative process. When divided parts come in contact with the air, the adhesion is always formed in this manner,—by the suppurative process,—whatever may be the nature of the structure which is thus circumstanced; and the false membrane, which is the medium of union, becomes more thin, firm, and fibrous, and, at the same time, less apparent with the lapse of time. This may be called *consecutive* adhesion. When the divided surfaces are protected from the air, and primary adhesion takes place, the process is more rapid; but its quickness will depend upon the quantity of blood effused between the divided surfaces. If this be considerable, one of two things will result,—either the effused blood will be absorbed, and a cyst, or cellulo-fibrous medium of union, be slowly formed, which will be gradually diminished in thickness; or the coagulum may act as a foreign substance, keep up irritation of the vessels in the divided surfaces, and cause suppuration, and consecutive adhesion with the cicatrix formed by the medium of union. (See art. *ABSCESS*.)

8. There is one important point connected with adhesions in their various states and seats,—whether *reparative* or *morbid*, whether *primarily* reparative or *consecutively* reparative, and whether taking place between cellular, serous, or other structures,—which has not received the attention from modern pathologists that its practical importance requires for it, and to which JOHN HUNTER first directed notice. I allude to the important truth, that adhesions of either of the above descriptions, but particularly the primary reparative, whether taking place between divided surfaces or around purulent formations, either will not form, or, if in the process of formation, will be dissolved, in certain states of the vital energies of the frame, and of the circulating fluid. Great depression of the vital influence will have this effect, whether it be produced by the exhaustion proceeding from profuse discharges, by contagious and other noxious miasms, by the close air of hospitals, and other places loaded with animal effluvia, by the inoculation of certain animal poisons, by the absorption of puriform or sanious secretions, or other morbid matters, into the current of the circulation, by the mercurial affection of the frame, or by the gouty diathesis. When the vital energies of the frame are greatly depressed, and the tonic action of the capillaries much relaxed, by causes acting either extrinsically or intrinsically as respects the blood-vessels, the ability of throwing out a concretescible or coagulable lymph from the divided or inflamed vessels is destroyed, and in its place is produced an ichorous serum, or sanious fluid, which may either pass out, or, if no ready outlet is afforded, will infiltrate itself through the tissues adjoining, or be partially absorbed and vitiate the perhaps already morbid blood. (See art. *BLOOD*.)

9. In order to prevent this very dangerous state from supervening in all cases where the reparative process of adhesion is required, the utmost attention ought to be devoted to the state of the vital energies, particularly as indicated by the tone and frequency of the pulse, and the states of the digestive organs. When the former becomes

very quick, and the powers of the latter fail, that much dreaded state of the frame, which is insufficient for the formation of coagulable lymph, may be considered as approaching, if it be not actually present. In all cases where blood-vessels are liable to be inflamed, this state of the constitutional powers, owing to the risk of the blood being vitiated, is particularly to be guarded against. Having advanced as much as belongs to my province respecting the reparative states of adhesion, I proceed to state briefly the doctrine of *Morbid Adhesions*. The particular morbid adhesions are noticed under the articles on the pathology of the parts in which they form.

10. Adhesions in some one of the states described above (§ 1—4.) are liable to occur, as a consequence of certain grades of inflammation, in the following situations:—1st, In the cellular tissue; 2d, Between serous surfaces; 3d, Between mucous surfaces; 4th, Between synovial surfaces; 5th, In the internal surfaces of blood-vessels; and, 6th, Between the surfaces of morbid or accidental formations.

11. *A. Adhesions of Cellular Tissue.*—The first step of the process is the exhalation of a quantity of yellowish serum and of coagulable lymph into the cellulæ of this tissue, which ultimately agglutinates them together, upon the absorption of the former, and the concrecence of the latter. The consequence of this is, that the product of inflammation formed in the centre of the inflamed cellular tissue, consisting chiefly of the more fluid and least concrescible portion of the exhalation, is prevented from permeating the agglutinated cellulæ, and a barrier is set up against it. If resolution takes place, and the purulent matter is absorbed, the surfaces of the cavity become united, and the medium of union is changed, as in cases of recent wounds, and in the manner described above (§ 5.). If the parts go on to the evacuation of the matter, adhesion is also effected, as in the case of *consecutive restorative adhesion* (§ 7.); leaving, however, a cicatrix, which is gradually diminished, formed of the cellulæ-fibrous medium of union. In all cases of inflammation of cellular tissues adhesion of the cellulæ, from the exhalation of a concrescible lymph, takes place; and it is this adhesion which forms the fibrous cysts to abscesses, isolates their contents from the surrounding structures, and in some respects excludes them from the economy. Adhesions of the cellulæ of this structure also strengthen the cysts of aneurisms, and form sero-fibrous cysts around foreign bodies that are accidentally lodged in it.

12. *B. Adhesions between serous surfaces* are the next most common; being formed through the medium, either of a more or less thick and firm inorganic albumen, in the form of a false membrane, or of this substance advanced to a more or less organised state, and assuming either the appearance of cellular tissue, with a surface partaking of the serous character, or one of the states about to be noticed. The organised nature of those adhesions has been denied by some; but the observations of STOLL, HUNTER, DUPUYTREN, BAILLIE, MECKEL, HOME, LOBSTEIN, CRUVEILLIER, GENDRIN, BARON, and others, who have traced blood-vessels in them, have put the question at rest. Adhesions occur most frequently between the pleura, next in the peritoneum, and

next to these in the pericardium. They are comparatively rare in the tunica vaginalis; and in the arachnoid they are still more rare.

13. It is not necessary to the formation of adhesions between opposite serous surfaces, that the pre-existing inflammation shall extend continuously to both. When the coagulable lymph is thrown out upon one of the two inflamed surfaces, —as, for instance, on the peritoneal surface of the small intestines, — it seems to act as an irritant to the opposite part of the omentum, with which it is brought in contact, inducing inflammation of that part only, and leaving the intervening surface both above and below it unaffected. The part thus irritated by the contact of the coagulable lymph, poured out by the part primarily affected opposite to it, becomes also inflamed, and exudes this concrescible fluid; and the inflammation thus secondarily induced in a part of the omentum, may advance to the external surface of the omental duplicature, and, by means of the exudation of this product of inflammation in that situation, excite a similar state of action in the directly opposite part of the peritoneum reflected over the abdominal parietes. Thus the inflammation and its consecutive adhesions may proceed, without the disease having affected any of the continuous surfaces intervening between them. A similar circumstance is sometimes observed in respect of the convex surface of the liver and peritoneal surface of the diaphragm. Inflammation, commencing in a part only of the former, will excite it in the part of the latter exactly opposite, and be followed by adhesion; and the inflammatory action, not infrequently extending upwards through the diaphragm to the diaphragmatic pleura, will be further followed by the exudation of coagulable lymph on its free surface, which, irritating that portion only of the pulmonic pleura opposite to, or in contact with it, will inflame that part, and form adhesions with it, without affecting the continuous surface intervening between, and surrounding the adherent parts. The unadhering cavity, however, not infrequently contains a turbid or flaky serum, with patches of false membrane, arising from a less acute state of inflammatory action in those parts of the serous surface immediately adjoining the adhesions. Thus it is not unusual to find, in cases of acute inflammation affecting either the peritoneum, pleura, or arachnoid, and limited to a particular part, a similar state of disease, and the same product, formed only in the parts opposite, and most nearly in contact; whilst the continuous surfaces surrounding them are either altogether sound, or much less affected; — most commonly only so far as to give rise to a serous exudation, or slight albuminous coating, in their immediate vicinity.

14. From this it will appear, that the near approach, and more especially the immediate contact, of opposite surfaces, and the want of motion between the one surface and the other, will favour the formation of adhesions: thus they are most frequent at the superior parts of the pleura, between the convex surface of the liver and the diaphragm, and the serous surfaces of parts included in herniæ. The different species of media, by which adhesions of serous surfaces are affected, are the following, according to M. CRUVEILLIER:—An inorganised false membrane; a filamentous adhesion, and a cellular adhesion,

in neither of which blood-vessels are evident; a permanent organised membrane; and a tuberculated membrane. All these originate in a concrescible lymph, as in adhesions of cellular tissues. (See art. on SEROUS MEMBRANES.)

15. C. Adhesions between *mucous surfaces* are not frequent. BICHAT denied the possibility of their occurrence, unless destruction of the mucous membrane had taken place. He was led to this conclusion more by the functions of this membrane in health and disease, than by observation of facts. There can be no doubt, however, that the opposite surfaces of canals, covered as they are by mucous membranes, occasionally adhere, in consequence of very acute attacks of inflammation; but this occurs very rarely, owing to the access of atmospheric air, to the presence of gases, to the various matters constantly passing through them, and to the nature of the fluid which usually proceeds from inflammation of these surfaces. The most common exception which takes place to the general inference adopted by BICHAT is met with in the vagina. I have observed several cases, at the Infirmary for Children, where adhesions of the opposite surfaces of this canal had taken place in consequence of inflammation, — some of them at so early a stage, that they were removed by merely forcibly separating the adherent surfaces, when the mucous membrane was found perfectly entire, but highly inflamed, and covered by an exudation similar to that which is thrown out upon inflamed serous membranes. Similar facts are recorded by M. M. DUPUYTREN, VILLERMÉ, BRESCHET, and CRUVELLIER. Adhesion also of the *os uteri*, as a consequence of inflammation, is sometimes observed. Occlusion of the Fallopian tubes, and even the adhesion of the opposite internal surfaces of the uterus, have been occasionally met with. WALTHER, RENAULDIN, and MECKEL observed these changes so often in prostitutes, that they attributed them to the frequent irritation of the parts, and imputed the barrenness of these females partly to this cause. But, in the cases of occlusion of the Fallopian tubes, more is to be imputed to the accumulation of an inspissated or albuminous mucus, the product of inflammation, which, from its tenacity and consistence, cannot flow along these tubes, than to actual organised adhesion of their opposite surfaces. The occasional occurrence of obliteration of the canals of the common bile-duct, and of the ureters from the impaction of a calculus, seems to proceed from the irritation and abrasion occasioned by calculi, and the consequent exudation of a concrescible fluid, which agglutinates their surfaces, and ultimately tends to reduce them to a cellulose-fibrous chord.

16. Adhesions are either never met with in the air-passages, or so rarely, as to render their actual occurrence doubtful. I believe that, although albuminous concretions are occasionally formed in the bronchi, and frequently in the trachea and larynx, &c., they cannot be so produced as to give rise to adhesions of the opposite surfaces. They never, or at least very rarely, become organised; and although they may completely obliterate the canals of several of the bronchi, they cannot have this effect on the trachea without causing immediate death. The organisation and form of the larger air-tubes completely prevent their adhesion; although they are often nearly

filled up with concrete albuminous formations, as a consequence of certain states of inflammation. Adhesions of the internal surface of the œsophagus, or of any other part of the digestive tube, are never met with; although constriction, with thickening, &c. to the almost entire obliteration of this canal, is not infrequent. As in the air-passages, nature has made in the functions, during health and disease, of the membranes which line them, sufficient provision to prevent this lesion from occurring. And we uniformly observe, when inflammation attacks any portion of those tubes, the preservation of the canal of which is essential to life, that, although a copious albuminous exudation will sometimes occur, its organisation will generally be prevented, and its detachment from the surface on which it is formed will be secured, sooner or later, by the secretion of a more fluid, or mucous, or muco-purulent matter underneath, which loosens the concrete albuminous coating or false membrane from its attachment to the surface on which it is formed. The circumstances which chiefly seem to favour the formation of adhesions between mucous surfaces, are — 1st, The abrasion of the epidermis which covers them; owing to which their secretions are changed, and they partake more of the characters of cellular tissue. 2d, Entire destruction of the mucous membrane in a great part, or the whole, of the circumference of a canal, favouring its gradual constriction, suppuration, and ultimate obliteration. The bile-ducts, ureters, urethra, rectum, and œsophagus occasionally furnish proofs of this change in some one of its stages. (See art. on MUCOUS MEMBRANES.)

17. D. Adhesions of the *synovial surfaces* of joints are rarely observed, excepting in cases of ankylosis, of which they cannot be considered even as the commencement, although they may accompany the earlier stages of this change, particularly in ankyloses consequent upon rheumatism. Many, however, of the alterations which take place in the synovial apparatus of tendons are consequent upon their adhesion and obliteration. Inflammation occurring in them primarily, or extending to them from contiguous parts, is generally followed by their adhesion, and reduction to a state of dense cellular tissue. Hygroma almost always terminates by adhesion.

18. E. The adhesion of the internal surface of *blood-vessels* takes place through the medium of the coagulated lymph secreted by the inflamed *va-vasorum*. The vessel becomes impervious in consequence of this exudation, which is poured out in the form of a false membrane from its internal surface. The lymph which is exuded, particularly when its coagulable or concrescible property is well marked, frequently produces coagulation of the blood in contact with it; so that, generally, the obliteration is occasioned both by this lymph, and the coagulum of blood which it occasions. In a short time the coagulum thus formed within the inflamed blood-vessel becomes more and more pale and dense, sometimes partially organised; and, as its density is increased, so is its bulk diminished: the coats of the vessel, at the same time, lose their specific characters; they seem constricted around the substance formed within them, the middle coat becomes less distinctly fibrous, and at last they are reduced to the state of a cellular, or fibro-cellular, chord.

This may be viewed as the primary form of their adhesions, and its usual results. When, however, suppuration takes place in their internal surface, the adhesion is formed consecutively in the manner described above (§ 7.); or the primary may pass into the consecutive form of adhesion, particularly when the false membrane is insufficient to fill up the entire canal of the vessel.

19. Adhesions take place more readily in veins than arteries; are produced in both, and in lymphatics also, in the manner now stated, generally in consequence of inflammatory action, attended with sufficient power of the constitution to form concrescible lymph (see the articles on ARTERIES and on VEINS); and sometimes, even after a very slow and slight grade of this action, when the opposite surfaces of the vessels are pressed together by any tumour existing exteriorly to them. When artificially excited in arteries, as by the application of ligatures, the inflammatory state which produces the adhesion is not so prone to extend along the axis of the vessel, or to occasion dangerous effects, as when it is excited in the same way in veins. When thus produced in these latter vessels, fault of constitution, an unhealthy habit of body, unwholesome state of the atmosphere, &c., or the other causes above assigned (§ 8.), will generally interfere with the process, and occasion that state of morbid action, and of its products, which will vitiate the current of the circulation, and even destroy life. (See VEINS—*Inflammation of.*)

20. F. Adhesions of the internal surfaces of cysts, and other morbid formations, sometimes take place from a consecutive state of inflammation extending to them. Large cysts, which in consequence of their situation cannot be removed, may be obliterated by their puncture, and the production of inflammation of their internal surfaces, so as to procure their adhesion.

21. G. Adhesions may also form between parts of the cutaneous surface, when deprived of the cuticle, and kept in close contact. This is not infrequent after scalds and burns, and is produced in a similar manner, as I have explained, in respect of adhesions taking place primarily, and without suppuration, or subsequently to the occurrence of this process in the cellular and mucous tissues. Adhesions also occur in other situations, as between the iris and capsule of the crystalline lens, &c.; but I have noticed those which more especially belong to my province.

ADIPOSE TISSUE.—*Tela adiposa*, Lat. *Tissu graisseux*, Fr. *Das Fett*, Germ.—ITS MORBID STATES.

CLASSIF.—IV. CLASS, IV. ORDER (*Author*, see the *Preface*).

1. The adipose substance is frequently either *diminished* or *increased* far beyond the healthy standard.—A. Excessive diminution of this substance, *atrophy*, occurs naturally in very aged persons; and there seems to be, even in early life, a tendency to it hereditarily in certain constitutions, particularly in those of a peevish, anxious, and irritable temper. It is often met with as a consequence of, or conjointly with, pulmonary and other organic diseases, particularly those which interrupt assimilation and the supply of nutrition. But it is also a symptom of all diseases, which impair the vital energies by morbidly increasing the secretions and evacuations; as in diabetes, diarrhoea, and dysentery. It also necessarily proceeds from long abstinence, &c.

2. Atrophy of this substance may be temporary or permanent. It is usually the former in early or middle life, and continues merely as long as the causes which occasioned it. It is usually permanent in advanced life, and in those of an active, peevish, restless disposition. In every case the removal of the fatty matter is produced by absorption; and, according to the experiments of MAGENDIE, TIEDEMANN, GMELIN, MAYER, &c., this process may be ascribed, at least in part, to the minute veins. The circumstance of fatty and oily matter being constantly found in the blood, but in variable quantity, as shown by TRAIL, BABINGTON, LE CANU, &c., seems to support this view; for, if taken up by the absorbents, it may have been changed or assimilated in its passage through the absorbent glands before it could have reached the blood.

3. B. *Excessive deposition* or *hypertrophy* of this substance (*adiposis*) is very common, affecting the body generally, but sometimes locally only. Persons have weighed as much as 500 or 600 lbs. owing entirely to this state of hypertrophy. This tissue is naturally abundant in females and eunuchs. Its hypertrophy is frequently occasioned by excessive venereal indulgences, particularly in early life, and when conjoined with high living and indolence. It generally is attended by a weak languid circulation, weak digestion, with craving appetite, defective secretions and excretions, and disinclination to active mental or physical exertion. It also evinces a marked hereditary character. Full living, particularly on food which abounds with the elements of the fatty substance as sugar, spirituous and malt liquors, &c., tend greatly to promote it. The connection of this morbid state with deficient assimilation appears fully proved. It would seem that in persons whose vital energies are diminished, whilst the appetite remains unimpaired, or is excited by stimulating liquors, &c., the sanguification of chyle does not take place so rapidly nor so perfectly as in health; that a large portion of this fluid assumes an oily or fatty character, and is deposited in the adipose tissue, which thus becomes one of the emunctories of the frame, in which a substance that cannot readily be carried out of the circulation by any other organ is set apart for the purpose of future absorption, assimilation, and nutrition, as the wants of the system may require, and to prevent its hurtful accumulation in the circulating fluid. Thus, in persons otherwise apparently healthy, the excessive accumulation of fat is often one of the earliest and most remark-

able signs of diminution of the vital energies of the frame. (See art. *OBESITY*.)

4. C. In many instances, when the powers of the constitution are either greatly reduced or otherwise perverted from the healthy state, the adipose matter is also changed in colour, composition, and consistence, becoming remarkably pale, or dark, reddish, or gelatinous. It may likewise be, particularly in cachectic persons, uncommonly watery, soft, smeary, or jelly-like; and on the contrary, but more rarely, hard, waxy, or even horny.

5. D. It may be a question whether or not this tissue is liable to inflammation. Considering it merely as a modification of the cellular structure, chiefly in as far as it contains the fatty substance of the body deposited in its areolæ, the containing tissue only must be looked upon as that which is liable to inflammation or any other disease; the fat or contained matter being entirely passive, and modified only by the morbid states of the tissue which secretes and contains it. There seems little doubt that the adipose tissue participates in the various states of diffuse inflammation; whether that attending upon certain forms of erysipelas, or following accidents, or the inoculation of morbid matter. When thus inflamed, it rapidly passes into a state of sloughy and fetid suppuration; large portions of it being not infrequently converted into an ash-coloured, semifluid pulp, mixed with shreds of cellular tissue and albuminous matter, or becoming entirely sphacelated.

6. E. *Effusion of blood* into the adipose tissue occurs under similar circumstances to those connected with hæmorrhage into the cellular substance, but much less frequently. This change has been occasionally noticed by HUXHAM, CLEGGHORN, CRAIGIE, and by myself and others, in scorbutus, purpura hæmorrhagica, and in the liquecent or malignant forms of remittent fever in warm or unhealthy climates.

7. F. Of the tumours most frequently developed in this tissue, the most remarkable are — a. *Adipose sarcoma*, which is surrounded by a thin capsule of cellular tissue condensed around it, and consists of an unusual accumulation of fatty matter in cells, the component fibres of which are so firm as to give consistence to the tumour: it closely resembles a local hypertrophy of the adipose tissue, excepting that it is surrounded by a capsule; and it may have either a broad or narrow base; — b. *Steatomatous* tumours are chiefly a peculiar modification of the fatty secretion, which is accumulated in masses, surrounded by a spheroidal cyst: they are not formed of cells, in which the fatty matter is deposited, but consist of a simple semifluid substance secreted by the inner surface of the cyst: they occur more frequently in the cellular, than in the adipose tissue; — c. *Atheromatous* and *melliferous* tumours are either modifications of the steatomatous, or proceed from the change induced in small chronic abscesses; but they are most commonly the former when seated in this tissue.

8. G. *Melanoid* deposition is sometimes found both in the internal and external adipose substance. It may be either disseminated in the form of small inky spots, or accumulated in spheroidal masses; or found in a semifluid state and brownish black colour, surrounded by a cyst formed by the condensation of the contiguous cellular tissue. As to the state in which this peculiar matter is formed, great diversity of opinion exists. LAENNEC sup-

posed that it is first secreted in a solid form, and, like tubercular deposits, afterwards becomes soft. I am, however, inclined to adopt the opposite opinion; viz. that it is secreted in a fluid or semifluid state, and that it afterwards becomes firm by the absorption of its more fluid parts. The observations of Drs. CULLEN and CARSWELL, and of M. CHOMEL, seem to confirm this opinion.

AFTER-PAINS. SYN. *Parodynia Secundaria Dolorosa*, Good.

CLASSIF.—5. Class, 3. Order (Good). II. CLASS, III. ORDER (Author).

1. DEFIN.—*Pains, more or less severe, either continuing or supervening shortly after the expulsion of the placenta in child-birth.*

2. 1. SYMPTOMS AND DIAGNOSIS.—Attacks of pain in the abdomen are usually experienced in the early part of the puerperal state. They proceed, when very severe, from the contraction of the uterus, irregularly excited by the presence of coagula. They usually soon follow delivery, are least severe after a first labour, are increased upon the application of the child to the breast, and last for a day or two. They are generally aggravated by flatulence and costiveness.

3. It is extremely requisite for the young practitioner to be on his guard respecting the nature and seat of pain after delivery, as the commencement of the most fatal diseases to which the sex are liable may be mistaken, if not carefully observed, for after-pains. These latter are the result of the natural contractions of the womb, and of its return to its former state; and are distinguished from disease, particularly inflammations of the uterus, ovaria, or pelvic peritoneum, by their remissions, and by the absence of tenderness or tension of the abdomen, especially on pressure. The uterine discharge, also, is not obstructed; the milk is secreted; there is no shivering nor vomiting; and the pulse is seldom increased in frequency.

4. When the patient's bowels have been neglected previously to confinement, and when much flatulence exists, the after-pains are often complicated with colic, or they assume a colicky character. In cases of this kind, the abdomen is often somewhat more tense and distended than usual; the fits of pain are severe, with complete remissions; the patient complains of flatulence; the bowels are constipated: but the pulse is not much affected; the skin, particularly of the trunk, is not hot; the tongue is moist; and the feet are often cold; in a few cases there is retching. It is important to attend carefully to the character of pain consequent upon delivery, and to consider it in relation to the attendant symptoms, particularly the states of the pulse, and of the abdomen. We ought, therefore, to inquire into its exact seat, examine the pained part carefully with the hand; and, having ascertained in what manner it is affected by the examination, we readily arrive at just conclusions as to its nature. When it is felt in the regions of the uterus and ovaria, and accompanied by great fre-

quency of pulse, disorder of the lochial discharge, tenderness, and fulness of the hypogastric region, &c., the existence of the inflammatory diseases of the uterus, and of its appendages, are to be inferred. If it be complained of about the groin, it may be the forerunner of phlegmasia dolens; and if it be felt about the hip, or in the muscles of the pelvis, abdomen, or thighs, it may be rheumatic, owing to the application of cold in some form or other. The pains of rheumatism are readily recognised from their seat, their aching or gnawing character, the manner of their affecting the motions of the part, and the attendant symptoms. The diagnosis, however, of these diseases is fully pointed out under their respective heads.

5. II. TREATMENT.—The exhibition of an anodyne, with attention to the state of the bowels subsequently, has generally been considered sufficient for the relief of after-pains. In the more severe cases, an anodyne liniment has been recommended to be applied to the abdomen, in addition to the exhibition of a dose of laudanum internally; and, in protracted cases, Dr. Burns advises a purgative—certainly the best part of the treatment usually resorted to. I am, however, of opinion, from remarking the results of this practice, that the common or less urgent cases would have been better left to nature; and that friction of the abdomen merely with any of the liniments in the *Appendix* (F. 297, 298.), or friction followed by a purgative, or an enema, is all that is necessary. We ought to recollect that these pains are merely the result of the healthy tonic contractions of the uterus upon the congested veins, and the coagula remaining in it, occasioning their expulsion, and the discharge of the blood accumulated in its sinuses; and that the more effectually these ends are accomplished, particularly in unhealthy situations, and lying-in hospitals, the less risk there will be of the occurrence of dangerous forms of puerperal disease.

6. Whilst, however, anodynes allay the morbid sensibility of the uterus, they tend to diminish its tonic contraction, to induce a congested and relaxed state of its parietes and mouth, and to favour the admission of air into its cavity. Air, when admitted, particularly under certain circumstances, is productive of the most dangerous results, from its effects upon that portion of the surface of the womb to which the placenta was attached. Impressed with the justness of this view, I have usually recommended frictions with liniments over the region of the uterus, and a purgative, or purgative injection, which will tend essentially to favour the contraction of the uterus, and the expulsion of the cause of irritation.

7. In cases complicated with flatulency and colic (§ 4.), the above means are still more requisite; but much will depend upon the choice of purgatives. My own experience, derived entirely from consultation, is decidedly in favour of a draught, consisting of half an ounce of the oleum terebinthinæ, combined with the same quantity of oleum ricini; or an enema, containing the same medicines. The combination, also, of a purgative with assafœtida, or any other antispasmodic, and an injection, consisting of infusion of valerian, or containing assafœtida, with a due proportion of any aperient medicine (see F. 130. 135. 138.), will seldom fail of giving relief,

by removing flatus, and promoting the restoration of the uterus to its natural state. In the more urgent cases, anodynes may be conjoined to the foregoing means; for, when thus associated, they will not act in preventing the contractions of the uterus. (For Hysteralgia, and the various diseases of the uterus in the puerperal and unimpregnated states, see UTERUS.)

AGE.—SYN.—*Ætas*, Lat. *Das Alter*, Ger. *Age*, Fr. *Êta*, Ital.

CLASSIF.—PATHOLOGY AND THERAPEUTICS.

I. In the succinct view I propose to take of the pathological and therapeutical indications which this subject will naturally suggest to the mind of the practical physician, I propose, *first*, to sketch the successive epochs of life, and thus consider the word in its generic acceptance. When I arrive at those periods of existence to which the word *age* is specifically applicable, the changes which take place in the human frame, in respect both of organisation and function, with the advanced progress of years,—with age in its specific acceptance, will be fully stated, as furnishing important data for practical indications in the treatment of diseases of this epoch.

2. I. OF AGE IN ITS GENERIC ACCEPTATION, —or different Epochs of Life.—Before I proceed to consider the subject in its enlarged point of view, I may briefly advert to the periods into which the usual natural duration of human existence may be divided. Without occupying my limits with the divisions adopted by ancient and modern writers, I shall adopt that arrangement of the different epochs of life which has been suggested to my own mind, from observing the varying manifestations of life and function, and the modifications of diseased action with advancing age. The division which I have thus adopted may require more to be said in support and illustration of it, particularly in respect of its physiological relations, than I am willing to advance on a subject which may be considered as nearly verging on the speculative. Leaving, therefore, out of sight many of the physiological and psychological views, which would arise out of an extended investigation of the subject, I shall merely briefly advert to topics of practical importance;—those which concern the medical jurist fall not within the scope of this work. (For epoch of *fœtal life*, see FÆTUS.)

3. Before proceeding to consider the different periods of age individually, it may be useful to exhibit a view of the arrangement I intend to follow:—

i. PERIOD, or that of *Infancy*.

1st *Epoch*, to the commencement of the first dentition.

2d *Epoch*, from the commencement, to the completion, of the first dentition.

ii. PERIOD, or that of *Childhood*.

Extending from the completion of the first to the completion of the second dentition.

iii. PERIOD, or *Boyhood*—*Girlhood*.

From the seventh or eighth year to the commencement of puberty.

iv. PERIOD, or *Adolescence*.

Commencing with the first appearance of puberty, and extending to adult age.

v. PERIOD, *Adult Age*.

1st *Epoch*, or early adult age, or confirmed virility.

2d *Epoch*, or mature age.

vi. PERIOD, *Declining Age*.

1st *Epoch*, declining age.

2d *Epoch*, advanced age.

vii. PERIOD, *Old Age*.

1st *Epoch*, ripe old age.

2d *Epoch*, decrepitude — second infancy.

4. i. PERIOD, or that of INFANCY, (*Infantia*, from the privation of speech,) commences with birth, and extends to about the end of the second year, when the first dentition is completed. It may be divided into two epochs; the *first* beginning at birth, and extending to the sixth or seventh month, when dentition is fully commenced; the *second* proceeding from this age to the end of the period, the completion of the first dentition, when the relations of the young being with the external world are fully established by the development of the sensorial and locomotive organs.

5. A. During the *first* epoch, or that preceding the commencement of dentition, all the structures are merely in the course of development; particularly the osseous system, the cerebro-spinal nervous system, and the organs of locomotion. The functions are only acquiring activity, and several of them have not yet appeared. The vital phenomena gain strength, whilst certain of those functions, by which the young being is to hold converse with the objects around him, either begin to dawn, or have not yet merged into existence. The manifestations of life are chiefly vegetative, and the movements automatic or sympathetic. The *attitudes* are generally without variety, and the changes of the countenance express merely pleasure and pain to the spectator; but, to the medical observer, they convey important information, and often all that he can obtain respecting the maladies incidental to this period of life. At this epoch, the position of the limbs, the character of their motions; the cry, and its numerous varieties; and especially the changes of the countenance; the state of the eyes and eyelids; the openness, contraction, &c., of the eyebrows; the appearance of the lips and nostrils, of the mouth, gums, and tongue; — all furnish means of ascertaining the nature and progress of disease.

6. a. At this stage the organs of digestion are unsuited to any other food than that derived from the breast of the mother; and so little capable are they to assimilate any other, even of the blandest and most digestible kind, or the milk of other animals, that very few, not more than one in six or seven, ever arrive at the more advanced periods of life who are deprived of the kind of nourishment nature intended for this epoch. At this age the system is extremely susceptible of external impressions acting upon the lungs, surface of the body, and digestive organs; and particularly to the influence of cold. Recently removed from a constant and unvaried warmth, and having heretofore existed with all the mucous surfaces shut from the action of foreign agents, the young infant imperatively requires to be pre-

served, particularly during the first months of this epoch, from the influence of a low range of temperature, and from its sudden changes. The disposition to increased action in all the mucous membranes, and the great susceptibility of the respiratory nerves, require the surface of the body, and particularly the organs of respiration, to be guarded from atmospheric vicissitudes; the chief source of the diseases which are so prevalent and fatal at this age. A similar susceptibility of the digestive mucous surface also exists, and is but too frequently evinced by the slightest change in the milk of the mother, or addition of articles of food unsuited to the state of the digestive organs. Much of the mischief, however, which improper ingesta are calculated to produce, is guarded against by the copious secretion of mucus, with which the internal surface of the stomach and bowels is covered, particularly in very early life.

7. The susceptibility of the mucous tissues to stimuli and irritants, and their proneness to inflammatory action at this age, extend also to the cutaneous surface, as shown by the frequency of acute exanthematous diseases, and of chronic eruptions. The intimate sympathy existing between both these structures is very strikingly evinced, by the frequent association of inflammatory excitement of the mucous surfaces, particularly of the digestive canal, with a similar affection of the skin. The co-existence and close connection of inflammatory irritation of the digestive mucous surface, and an analogous state of disease of the brain and its membranes, or the supervention of the latter on the former, are also often observed. During the first months of existence, vascular action in the brain is prominently developed, and engaged in perfecting the organisation of this organ; and partly owing to this circumstance, as well as to the quantity of blood sent to it, compared with the rest of the body, and to the various causes tending at this age to derange its circulation, is readily kindled into an inflammatory state of its substance or membranes, giving rise to active congestions, effusions of fluid in the cavities and between the membranes, and to various other organic changes particularised in their appropriate articles.

8. b. With the susceptibility to be impressed by the causes of disease, evinced chiefly in the nervous centres and mucous surfaces, and producing their effects, not only on them but also on the serous cavities, there is intimately connected a marked disposition to be affected by medicines, which exert their influence in an especial manner upon the nervous system. Of these the most remarkable are narcotics and irritating stimulants. The susceptibility to the influence of the former, particularly the preparations of opium, and their effects, primarily in increasing vascular action in the brain, and secondarily in favouring congestion in the same organ, according to the dose, have appeared to me so important, that, during an extensive public practice amongst this class of subjects, I have scarcely ever ventured, during this epoch, on the exhibition of these medicines, excepting under peculiar circumstances, which will receive a more particular notice in other places. A similar caution is also necessary in the use of stimulating and irritating substances. The aperient medicines which are so often re-

quired at this age should be chiefly of a mild and unirritating quality; and, whilst cold and moisture must be avoided, too warm clothing, particularly of the head, ought to be equally shunned. Exposure to a mild, healthy air, frequent ablutions of the surface with cold water during the latter part of this epoch, — commencing first with warm water, and passing on to the use of tepid, and afterwards of cold water, as the infant increases in strength, — followed by frictions, and careful attention to the state of its evacuations, are means which should not be omitted in the management of this period of life. Although cold bathing is generally beneficial after the first months of infancy have elapsed, care should be taken not to subject the infant to the influence of cold beyond a minute or two, or longer than may be requisite to the perfect ablation of the surface; for, at this epoch especially, the impression of cold continued for any considerable time depresses the vital energies, and prevents the development of that state of healthy secretion on the surface, which usually follows the momentary or brief action of cold, particularly when followed by dry frictions.

9. *B.* The *second epoch* of this period, extending from the commencement of the first dentition to its completion, embraces also the important period of weaning. The natural changes proceeding in the different structures and functions during the *first* epoch also continue through this. As this period advances, the functions of external relation, particularly speech and voluntary locomotion, commence, the phenomena of perception are more perfect, and the manifestations of mind begin to appear. The instinctive desires and emotions become more and more evident and active, and furnish, with the other functions, important indications of disease, and of the means of removing it. The susceptibility of the nervous system, and of the mucous surfaces, to be impressed by the usual exciting causes of disease, — particularly by cold, moisture, atmospherical constitutions, and vicissitudes, contagious or infectious miasms, and errors of diet and regimen, — is unimpaired.

10. *a.* *Teething*, which terminates the preceding epoch, and ushers in this, is commonly connected with more or less disorder of the system. In infants of a healthy constitution, and in whom the powers of life are energetic, disorder is scarcely perceptible unless from the operation of very efficient causes; but in those who are debilitated, whose conformation has been originally feeble, or imbued with any hereditary taint or morbid diathesis, or who have been weakened by unwholesome food and impure air, this process is often attended with great disturbance in the frame, and, owing to the morbid sensibility and irritability it excites, frequently kindles up most dangerous disease. During the process of *teething*, particularly at its early stages, the itching and irritation of the gums are a constant source of excitement, or focus, whence irritation extends to the salivary apparatus, as proved by the increased flow of viscid saliva. The continued desire evinced by the little patient to allay the itching of the gums, by pressing between them whatever it can lay hold of, and the evident distress expressed by it if this sensation, which is known to be more insupportable than pain, can-

not be allayed, are indications which ought not to be overlooked. If this distressing sensation be not allayed by judicious means, the nervous system becomes inordinately excited, febrile commotion is induced, the functions of digestion are disordered; and we are, consequently, not infrequently called upon to remove inflammation of the membranes or substance of the brain, various convulsive affections, and inflammatory disorder of the digestive mucous surface, owing to the extension of irritation along the alimentary canal, as well as to the acidities formed in the stomach and bowels, from the imperfect digestion of the food. During dentition also, a marked disposition seems to exist in the pancreas to become excited, owing to its close sympathy with the salivary apparatus; and I am persuaded that several states of diarrhoea observed at this epoch originate in, or are perpetuated by, an increased secretion of pancreatic fluid.

11. Owing, moreover, to the excitement and irritation existing in the gums, affections of the respiratory and digestive mucous surfaces are more frequently associated with one another, and with increased vascular action in the nervous centres and their envelopes. It would seem that the irritation existing in the mouth disposes, from its influence on the nervous system, the mucous membranes not only to be invaded by the exciting causes of disease, but also to undergo the morbid action throughout. How frequently has the experienced practitioner observed inflammatory irritation of the digestive and of the respiratory mucous surfaces associated in the same case; and how often has he had cause to suspect the rapid supervention of irritation of the membranes of the brain, or of the brain itself, either with or without effusion, upon inflammation of the digestive mucous surface!

12. *b.* *Weaning*. — During this epoch *weaning* must take place. This should not be earlier than the eighth or ninth month, or later than the fifteenth; and the infant ought to have, at least, four teeth quite through the gums before it be commenced. The milk of the mother is the infant's only food during the greater part of the preceding epoch, or, at least, until the fourth or fifth month, unless the mother and child be in a weakly state. From this age upwards it requires food in addition to the nourishment afforded by the mother; but this must be given at first in small quantities, and not oftener than twice daily. As this period of weaning approaches, food in larger proportion, and increased frequency, is necessary; and as soon as it shall have got teeth to masticate animal food, this may be given it in small quantity, and at first only twice in the week. Animal diet is seldom required before the completion of the first year, or previous to weaning; afterwards it may be given in gradually increased frequency, as the termination of the epoch approaches.

13. Whilst the infant is liable to most of the maladies which affect it during the first months, it is now also exposed to the invasion of many more; owing to the excitement occasioned by teething, the state of the milk, particularly during the last months of lactation, and the errors in respect of both the quantity and quality of the food. At the same time, however, its vital energies are more developed, and its functions more

perfect; and thus increased resistance is opposed to the extension of disease, and to its disorganising effects. All infectious and exanthematous disorders are very prevalent at this age; and, in addition to the maladies of the mucous surfaces already alluded to, the lymphatic glands, particularly those of the abdomen and thorax, are frequently the seat of disease; and worms often begin to form, particularly after the period of lactation. At this age, also, owing to the changes in the infant's food, as well as to the irritation occasioned by dentition, the disorders which originate in depraved or imperfect digestion and assimilation are especially prevalent, particularly aphthæ, rickets, tubercules, marasmus, and tabes menterica, remittent fever, scrofula, and numerous cutaneous eruptions.

14. *c.* The *therapeutical* indications at this epoch chiefly relate to the care which is required to preserve the head cool, and ward off the vascular excitement to which it is liable. Anodynes are less injurious at this period than in that preceding it, and are often required, particularly in soothing the irritability of the nervous system arising either from difficult dentition, from the exhaustion occasioned by previous treatment, or by disease, and particularly in the advanced stages of whooping-cough and croup. The state of the gums requires particular attention; and where there is evidence of itching, this sensation requires to be allayed, first, in the way that nature points out, by pressing hard and smooth substances between the gums, as a coral, ivory ring, and what is best, a gold ring, when this may be directed. If the least appearance of local affection, as tumefaction, redness, &c., or even merely constitutional disturbance, manifest themselves, the gums should be freely and deeply scarified. Aperients of a mild and cooling nature, are often required during this epoch; and in it, as well as in the preceding, blisters, even for a few hours only, particularly when the respiratory mucous surface is obstructed and its functions interrupted, or when the energies are exhausted and the vital resistance consequently reduced, must be employed with extreme caution, and give place to the use of those liniments which I shall have occasion to recommend as substitutes for them under such circumstances.

15. *ii.* PERIOD, or that of CHILDHOOD (*Pæritia*), extends from about the second to the seventh or eighth year, when the second dentition is completed. During this period the development of the different textures and organs proceeds rapidly, and their functions are more and more perfect. The mental manifestations, particularly those which are intellectual, are developed, and the various moral emotions gain strength. The distinctions which exist between sexes throughout the whole physical and mental constitution at more advanced ages have not yet appeared. All the soft solids of the body evince increasing firmness, vital cohesion, and elasticity, and are protected by a firm covering of adipose matter below the integuments, and in the interstices between the muscles.

16. *a.* If the constitution be not vitiated by hereditary or acquired taint, defective nourishment, or previous ailment, or if the causes be not of a depressing nature, disease at this period assumes the sthenic character. Febrile diseases

are generally acute; and, unless proceeding from sources of infection, usually the result of local inflammatory action, which evinces a marked disposition to terminate in the formative process, or effusion of coagulable lymph, particularly when the serous surfaces are implicated. The susceptibility to infectious diseases, particularly those with exanthematous symptoms, is very great; as well as to inflammations of the different textures and organs—to pneumonia, bronchitis, cerebritis, meningitis, gastritis, enteritis, &c.; besides these, glandular obstructions, chorea, verminous diseases, epilepsy, and the various forms of angina, are very prevalent at this age, particularly in those whose digestive organs have been neglected, and when morbid matters have been allowed to accumulate in the *prima via*.

17. *b.* The *therapeutical* indications applicable to this age present few peculiarities, besides the necessity of resorting to active depletions, with a cooling regimen and alvine evacuations in the majority of its diseases; and the keeping in recollection the tendency of mucous sordes and secretions to form and accumulate on the digestive mucous surface. Such accumulations furnish a nidus for the generation of worms, and sources of irritation to this surface itself, and to the nerves proceeding from it; and originate many of the affections which appear at this, and a subsequent period of existence. The necessity of enjoying, and the injurious consequences of the privation, of wholesome nourishment and active exercise in a pure atmosphere, and the advantages of sleeping alone in a large well-ventilated apartment, should not be overlooked, in their relation both to the production and to the removal of disorder. The employment of the faculties of the mind during this early stage of their development should be left, until the last year or two of this period, more as a matter of amusement than of exertion; and, even then, greater attention should be paid to the development of the physical powers,—the organisation upon which sound mental manifestations very intimately depend,—than to the precocious and even hurtful excitement of faculties which are merely budding into existence. The emotions of mind, however, particularly those which are connected with temper and disposition, ought first to receive attention; strict control cannot be prematurely applied in this direction. In this and the preceding epochs of life, it is indispensably requisite not to allow the child to sleep with persons in bad health, or who are far advanced in life.

18. *iii.* PERIOD, or BOYHOOD — GIRLHOOD. — From the seventh or eighth year to the epoch of commencing puberty, is chiefly characterised by the continued growth of all the structures, and the development of the manifestations of mind. Towards the middle and end of this period, the physical and mental distinctions of sex become more and more apparent. — *a.* The frame, when free from disease or hereditary taint, evinces a sthenic diathesis, a predominance of the sanguine, or sanguineo-nervous temperament, and a liability to nearly the same diseases, particularly those proceeding from infection and inflammation, that prevail during childhood. There is a greater liability to be affected with idiopathic-continued fever, with scrofulous enlargements and inflam-

mations, particularly of the lymphatic glands; with various nervous affections, as epilepsy, convulsions, chorea, &c.; with cutaneous eruptions; with inflammations of the throat and air-passages; with tubercles, especially in the lungs and alimentary canal; with flexures of the spinal column, and with verminous diseases. The nervous system possesses great susceptibility of impressions, moral and physical; and inflammatory action has a marked disposition to give rise to new formations, unless when appearing in the advanced stages, or as a sequela, of eruptive or infectious fevers, when it generally occasions serous or sero-albuminous effusions.

19. *b.* These diseases of this period generally require antiphlogistic remedies and evacuations, especially purgatives, either alone or in suitable combination, unless proceeding from depressing causes, particularly those of a specific kind; and even there the necessity of resorting to alvine evacuations, by means of laxatives, or purgatives combined with tonics, is imperative. The vital resistance is usually well marked, excepting in those who have been deprived of wholesome nourishment and pure air, or whose constitutions are radically in fault; and in these, whilst tonics and other means of restoration are required, the due evacuations of morbid secretions and accumulations is equally necessary. Care also should be taken during this, as well as in the preceding period, not to allow the young to sleep in the same bed with the old, nor even with those advanced in age or debilitated, nor with too many — not more than three — in the same sleeping apartment, which ought to be large and well aired. Want of attention to this, is one of the chief causes of disease in early life in London and other large towns. Academies and boarding schools for both sexes are continually furnishing numerous proofs of this too generally overlooked cause of disease, not only at this, but also at a later stage of life. Attention is also necessary to the exercises of both the mind and the body. Active amusements in the open air are now particularly required. As this period advances, the mental powers acquire such a degree of development as to admit of their further improvement and active exertion, — not only without risk to the organisation with which they are related, but with the certain prospect of advancing them nearer to the perfection to which our natures may attain.

20. During this and the earlier terms of life frequent changes of locality and of air, particularly from one healthy and open situation to another, and especially to one which is more salubrious, where this can be attained, are extremely beneficial, both in promoting the development of the frame and in removing diseases, particularly those of a chronic kind, or which affect the digestive and assimilating organs. In many of these diseases more advantage has been derived from change of air than from the use of medicine. But, during advanced convalescence from these and febrile diseases, the benefit obtained from change of locality is most remarkable.

21. *iv.* PERIOD, or ADOLESCENCE, commences with the first appearance of puberty, and extends to the twentieth year of females, and the twenty-fourth of males. Puberty appears at various

ages, according to the climate, the circumstances connected with education, and the constitution of the individual. The usual period in this country, is from the twelfth to the fourteenth year for females; and from the fourteenth to the sixteenth for males. In the northern parts of the island, it is often a year or two later in both sexes. It is often observed earlier in boarding-schools, both in respect of males and females. In the latter (in London or its vicinity), I have not infrequently met with instances of menstruation at ten and eleven years; especially in sanguine and plethoric constitutions; and where the apartments, particularly those for sleeping, have been crowded and close.

22. *a.* This is one of the most important epochs of human existence: for during it the natural development of the sexual organs imparts a healthy and tonic excitement throughout the economy; bringing to their state of full perfection all the organs of the body and all the manifestations of mind, excepting those that are derived from experience. The organs of respiration and voice have acquired their full growth and tone, the muscles their due proportion, and the cerebro-spinal nervous system its beautiful organisation; placing man, by the exercise of its admirable functions, at the head of all animated creation, — the dread of all other animals, the wonder of himself. It is chiefly during this period of life that the mind becomes stored with ideas, derived both from the learning of the ancients, the science of the moderns, and the arts and accomplishments of highly civilised life; and is more particularly and more ardently engaged in decomposing the information thus acquired, and recombining it in new and useful and attractive forms.

23. As the functions and destinies of this period are important, so they require the supervision of the experienced and the good. For, with this development and activity of both the physical and mental powers, the instinctive feelings and emotions of our nature have also reached the utmost limits of their activity; and many of them, particularly those which are related to the perfect condition of the reproductive organs, acquire an ascendancy, that both the dictates of reason and moral restraint are required to control. Hence the propriety, both at this and the preceding period of life, of improving the moral affections of the mind; of inculcating sound principles of action and conduct, founded on moral and religious obligations; and of placing them in such relations to the feelings, the intellectual manifestations, and, moreover, to the accomplishments, the elegancies, and the endearments of life, as to render them attractive to a state of mind and constitution which is more easily allured by example than taught by precept.

24. The evil practices which both sexes are liable to acquire at this period of life, and to which they more commonly become addicted, when they associate in numbers at seminaries and academies, demand the strictest prevention. They have been too generally overlooked, both morally and medically, from the circumstance of their consequences having been imperfectly appreciated. There is no practitioner of observation and experience, — none even of limited knowledge, — who is altogether unacquainted

with the physical exhaustion, the mental torpor, and all but annihilation of existence, which is the ultimate result of indulging them. From this source frequently spring, impotency hereafter; the extinction of families and hereditary honours — honours which such persons are incapable of achieving; the infiction, during after-life, of many of the diseases which proceed from debility, and the exhaustion of the nourishment and vital energy of the various structures and organs; numerous nervous and convulsive maladies, as hysteria, epilepsy, neuralgia, chorea, melancholia, mania, idiotey, &c.; the dangerous or fatal visitation of fevers, diseases of the heart, disorders of the digestive organs, premature baldness and old age, the formation of tubercles, and the production of pulmonary consumption; and, lastly, the transmission of weak and decrepit bodies and minds to the offspring, of scrofula, rickets, vermiform complaints, marasmus, hydrocephalus, convulsions, tubercles, chorea, &c.: the curse is visited on the children to the third and fourth generation, until the perpetuated punishment extinguishes the very name of the aggressor.

25. *b.* The *pathological* conditions of this age are especially characterised by exalted action. At the approach and commencement of puberty, the glandular system is extremely prone to congestive inflammations, particularly the lymphatic glands of the neck and armpits. Tubercles are rapidly developed in the lungs; and these organs are much disposed to acute and chronic inflammations of both their substance and mucous surfaces. Pulmonary hæmorrhages usurp the place of the epistaxis of earlier epochs; and, in females, dysmenorrhœa, protracted or retained menstruation, chlorosis, hysteria, and occasionally menorrhagia or leucorrhœa, occur. The sanguineous diathesis and plethoric habit, in those of a sound constitution, and the sanguine, irritable, and nervous temperaments, or the one associated with the other, most commonly prevail at this period of life.

26. The *progress* of disease is generally rapid, and its character acute. Inflammations are more prone to give rise to the formative processes; and febrile affections, when they terminate by crises, evince a preference to hæmorrhages and sweats. Idiopathic fevers, inflammations of the respiratory organs and of the brain or its membranes, are the most common diseases of this age.

27. *c* The *therapeutical* indications require but little remark; for the system has now nearly, or altogether, reached its full growth; and the general inferences which guide the practitioner in the employment of remedial means have now reference, especially, to states of habit, constitutional powers, temperament, and diathesis, — physical manifestations, which are now, in a great measure, developed, but which acquire their most predominant characters in adult age. As the maladies of this period are frequently inflammatory, and evince a strong tendency to the formative process, and as the powers of life are now most energetic, vascular depletions, with the antiphlogistic regimen, are often required, and are well borne; excepting in those whose constitutions have been originally in fault, or who have greatly injured it by the injurious practice of masturbation, from which so many suffer, both at this and subsequent epochs of life.

28. *v.* *PERIOD.*—*ADULT AGE* may be divided into the epochs, 1st, of *early adult age*; and, 2d, of *mature age*, or *confirmed virility*. Of each of these I shall take a brief notice.

A. Early adult age may be dated from twenty to thirty in the female, and from twenty-four to thirty-five in the male. During this epoch, if the constitutional powers have not been injured previously, the whole frame and its individual organs continue to acquire strength; and, although the body has ceased to grow in height, it increases in bulk, particularly the muscles of voluntary motion, and the parietes of the large cavities. It is also more capable of enduring continued exertion and privations; its vital endurance and resistance being greater than during the period of adolescence. The features and expression of the face; the character, disposition, temperament, and diathesis, are more unfolded, and towards the termination of this period fully display their manifestations.

29. *B. Mature age*, or *confirmed virility*, may be considered as being from thirty to forty, or forty-five, in the female, and from thirty-four to forty-eight in the male. During this time of life, the features of the countenance fully assume those modifications of character arising from the influence of the passions and emotions of the mind; and the appetites, habits, and occupations of life imprint upon the frame generally certain appearances, arising from their continued influence on the constitution. The muscular organs, particularly the muscles of the extremities, are prominently marked; the chest fully developed; the body spare and active; the adipose structure extremely scanty, and the abdomen small, in those habitually devoted to laborious employments, not of a sedentary nature, and to active exercise, either on foot or horseback. The sedentary, those addicted to the indulgence of the appetites, and particularly those given to the gratifications of the table, have large abdomens, small extremities, and large depositions of adipose matter beneath the integuments, between the muscles, in the omentum, and surrounding the viscera, with a weak and defective development of the muscular parts. The studious present the chief marks of their occupations on the features of the countenance and character of the head; the appearance of the rest of the frame varying with the habits and indulgences with which study or the prosecution of science may be conjoined. At this period of life also the feelings, the anxieties, the disappointments, the losses, and the various moral emotions of life, begin to manifest those effects upon the frame, which become still more fully expressed during the following epoch.

30. This and the preceding period of adult age are, upon the whole, the most exempt of all others from disease; but about the age of forty, and still more so as the age of fifty is approached, the sanguineous circulation becomes more and more languid, particularly in the veins; hence the frequency of venous congestions and visceral obstructions, with the various diseases depending thereupon, particularly hæmorrhoids; bilious derangements; bilious and gastric fevers; inflammations; affections of the heart; apoplexy and paralysis; derangements of the stomach and liver; hæmatemesis; affections of the joints, as gout and

rheumatism; diseases of the urinary organs; hysteria and uterine disorders; hypochondriasis, and affections of the mind. At this period, therapeutical means require to be strictly regulated according to the sex, constitution, temperament, habits, and occupations of the affected.

31. II. AGE, IN ITS SPECIFIC ACCEPTATION, may be divided into two PERIODS, and these into four epochs: viz. 1st, *Declining age*; 2d, *Advanced age*; 3d, *Old age*; 4th, *Decrepitude*, or second infancy. Before I proceed to consider these individually, I will take a view of the changes which supervene with age in the structures and functions of the body.

AGE, in the specific acceptance of the word, may be considered as commencing when the vital energies of the different organs begin to decline, — when the maturity of life glides into decay. The period at which this change supervenes varies very much in different persons, according to their constitutions, employments, and habits during the earlier epochs of existence. In many it is so gradual as to be imperceptible; in others it is more obvious; and in some it is induced rapidly and remarkably, by mental anxieties and bodily disease. The usual period of its advent, in both sexes, and the different epochs into which age may be divided, will be stated in the sequel.

32. As age steals on, all the functions are performed more languidly than in earlier life. The energies of the ganglial system decline, as evinced by the digestive, circulating, and secretory functions, which it actuates. The sensibility of the cerebro-spinal system, and of its dependent organs; the acuteness of our intellectual powers, our moral emotions and affections, and the activity and strength of the locomotive organs,—all experience diminution, great in proportion to the advances of age.

In noticing the pathological and therapeutical relations of age, those changes of structure and of function which supervene with it will first receive attention; next, the different terms into which it may be divided, with those modifications which diseased actions generally assume in each term respectively, and those indications which should guide our practice in the diseases to which each is most obnoxious, will be briefly considered.

33. A. The modifications of structure produced by age are occasionally slight; but most commonly they are very remarkable, particularly in certain organs. In some parts they are scarcely perceptible, in others more obvious, consisting chiefly of increase of density; and in many they amount to actual change of texture.

The integuments, particularly those of the face, and the hair, are amongst the earliest parts to exhibit the advance of age; and they most obviously indicate the different stages of its progress. The integuments of the face seem more developed than in early or mature age. They are denser and thicker, especially the cutis vera and rete mucosum; which latter assumes also a somewhat darker tint. The skin appears more loosely attached to the parts underneath it, chiefly owing to the diminution of the subjacent fat, and shrinking of the other soft solids. Hence it appears, particularly in the face, neck, and hands, flaccid and wrinkled.

34. The hairs of the head are perhaps the first

to evince the commencement of age; and they present the most common indications of the progress of decay, either by a more or less complete change of colour, or a partial and general loss of them. The change of colour at first consists of a few white or grey hairs, scattered amongst those of a natural hue; but these gradually become more numerous, particularly on the temples, until the whole hair is altogether grey, and ultimately white and transparent. As this change proceeds, the hair also falls out, especially on the crown and forehead. There are, however, many circumstances which accelerate these phenomena, independently of age. Thus fevers, severe courses of mercury, masturbation, &c., will occasion the loss of the hair. But when it falls out from disease, the bulbous roots not being obliterated, its reproduction generally follows; whereas, when it is lost from old age or from masturbation, it is never reproduced. There are also various causes which occasion a change of its colour, particularly the depressing passions, intense application to study, anxieties of mind, venereal indulgences, &c., and which at the same time accelerate the loss of it. The change of colour, and subsequent loss of hair, seem to arise from deficient nutrition, and consequent atrophy, or destruction of the bulb, together with some change in the skin itself. In some cases it seems to arise from chronic disease of the rete mucosum and cuticle, as stated in the pathology of certain cutaneous affections.

35. The adipose and cellular tissues experience considerable change. The fatty deposit diminishes with the progress of age, and it sometimes becomes more fluid and watery, as well as of a deeper tint. The cellular tissue is somewhat denser, more fragile, and less elastic than in early life. In some situations it assumes a fibrous character, particularly that portion of it which invests the muscular fibres. The serous membranes are also more dense, more subject to ossific deposits, and their free surface drier than in early life. The mucous surfaces exhibit but little change, excepting as respects their greater paleness, and tendency to certain states of disease. The fibrous structures become more rigid, and in various parts the seat of ossific deposits. They also assume a deeper colour, and firmer and tougher consistence, whilst their physical cohesion is much increased as age advances.

36. The muscles of voluntary motion experience a very marked change, particularly at the advanced epochs of age. They are much diminished in bulk. Their fibres are more rigid, less readily influenced by stimuli, and less contractile than in early life. They are also less under the control of volition, much less energetic in their actions, more flaccid, and endowed with less vital tenacity. Their structure is also somewhat modified. They are paler, sometimes of a light yellow colour, and their fibres less distinct than in youth. The tendons and aponeurotic expansions of muscles, as well as the cellular tissue intervening, are often partially ossified. Portions of muscles, near their tendons, are sometimes converted into a tendinous structure; and the secretions poured into the sheaths of the tendons are remarkably diminished. From all these changes result the vacillating, embarrassed, and weak movements of the aged.

37. The *bones* acquire a dense structure, and even a somewhat increased size, particularly the bones of the head, the sutures of which become firmly united, first in the internal, and afterwards in the external surface. The *cartilages* are ossified, particularly those of the ribs. The intervertebral cartilages become hard, inelastic, and shrunk; hence the impaired flexibility of the spinal column, the bending forwards of the trunk, and diminished stature of aged persons.

38. The *blood-vessels* undergo very remarkable changes. The arteries are gradually diminished, in proportion to the bulk of the body, as age proceeds; and the predominance of the venous over the arterial system is more and more apparent. Whilst the arterial vessels become, on the one hand, more dense and rigid in their coats, their calibre diminished, their smaller ramifications altogether obliterated, and their *vasa vasorum* indistinct, the veins seem, on the other hand, somewhat thinner in their coats, more dilatible, and their calibre increased; they are also more tortuous, and hence their capacity is augmented; so that, although the quantity of blood contained in the body is diminished, particularly at the most advanced stages of life, about two thirds of it are contained in the veins. Besides those changes of capacity, the coats of the vessels present changes of structure. The arteries are liable to ossific and other deposits, rupture of their coats, &c.; the veins to varix, inflammation, &c.

39. The *brain and nerves* are also somewhat modified by age. The membranes of the former are generally slightly thickened and opaque. The bulk of the brain is diminished, and its substance firmer and tougher than natural, and less readily acted upon by chemical re-agents. The nerves seem to possess a diminished quantity of medullary substance, and their blood-vessels are indistinct. The *ganglia* become firmer, of a deeper colour, and smaller than in early life.

40. The *organs of sense* undergo important alterations. The eyes are changed chiefly by the diminished secretion of aqueous fluid into the anterior chamber, occasioning less prominence of the cornea, and a change of its refractive power. The crystalline lens acquires a yellowish tint, and is less transparent. The nerves of the eye, particularly the optic nerves and ophthalmic branch of the fifth pair, and the iris, are less sensible than before; and hence the dilatation of the pupil, the distant sight, and the confused appearance of near objects to aged persons. The ear experiences a change similar to that which takes place in the eye. The fluid occupying its internal cavities is diminished or altogether absorbed; and the auditory nerve rendered insensible to impressions, from this and other changes in the conditions necessary to its functions. The other organs of sense, particularly taste and smell, have also their sensibility similarly blunted.

41. But changes are not limited to the more elementary structures of the body; and organs of sense, the *viscera* of digestion, secretion, assimilation, sanguification, and generation undergo analogous alterations. The teeth loosen or decay; the gums are partially absorbed; and the jaws deprived of teeth and of their alveolæ, approximate more closely. Hence the projection of the chin, its approach to the nose, and diminished capacity of the mouth. To these causes are partly to be

imputed the change which takes place in the speech of the aged. The *stomach* and *bowels* are generally flaccid, owing to deficient contractility of their muscular coats; but the *liver, pancreas, and spleen* present but little change, excepting they are, or have been the seat of disease, unless slight atrophy, or enlargement and increased density. The *urinary organs* are more frequently altered; calculi are not infrequently met with in the tubuli uriniferi and pelvis of the kidneys; and the urinary bladder is generally thicker and firmer in its coats than in early life; the prostate gland is commonly somewhat enlarged.

42. The *lungs* are not necessarily changed by age, further than that they become less elastic, their air-cells enlarged, some of the bronchial ramifications more dilated, and portions of them emphysematous. They frequently, however, present the remains of antecedent disease. The *heart* partakes, although in a less remarkable manner, of the changes experienced by muscular parts. The tone and energy of its fibres are lowered; its structure is softer, more flaccid, and occasionally also paler. It is sometimes diminished in size; or some of its cavities are dilated, and their parietes thinned; and cartilaginous or ossific formations, or both, occur in parts of its internal surface, particularly in the valves.

43. The *organs of generation* experience a marked alteration. The *ovaria* shrink, become dense, and their vesicular structure changed. The *uterus* is diminished in bulk, unless it is the seat of organic disease, to which it is very liable, particularly at its mouth and neck. The *mammæ* also waste, are soft, pendulous, and lastly are entirely absorbed. The areolæ become dark, and the nipples shrink. At the commencement of age they are subject to congestions, indurations, and scirrhus disease. The *testes* shrink, or become soft and small, or even nearly disappear. The *penis* is shrunk, seldom experiences the vital turgescence, and lastly not at all; the faculty of generation having previously disappeared.

44. In this rapid sketch of the chief changes which the structures and organs of the body undergo from age, there are several phenomena which must strike the reader. The chief of these are, the gradually increased density of the different textures, and the consequent diminution of their watery or fluid constituents, as well as of the blood itself. In childhood and early life the textures are succulent, and the circulating fluid abundant. But as age advances, they acquire an increase of their physical cohesion, whilst their vital attraction is diminished. This increase of density and diminution of the fluid elements of the structures, with the progress of age, are constantly observed in the vegetable kingdom of nature; and, as we advance upwards, through the various grades and classes of animals, we find this principle strictly adhered to. In addition to this, another phenomenon is remarkable; namely, the redundancy of osseous matter, as evinced not only by the increased quantity of earthy matter in the bones and cartilages, but also by the deposition of this substance in the coats of the arteries and in other textures. Somewhat analogous to these formations, and sometimes even vicarious of them, is the abundance of sabulous deposits from the urine, frequently observed to occur either

during the secretion and retention of this fluid, or after its discharge.

45. Not only are the mechanical conditions of the different parts of the body modified by age, as now stated, but their chemical properties are also similarly affected. The gelatin disappears, or becomes changed to albumen; the fibrin is increased, and assumes a deeper hue, and is less easily affected by maceration or exposure to the air. The phosphate of lime is augmented, and often accumulates to a very hurtful extent, together with the other earthy salts and urea.

46. *B. Of the conditions of function characterising the advance of age.*—*a.* Although the changes, which have been now described as supervening in the different structures with age, may have originated in those imperceptible and slow modifications which the various organic functions experience from peculiarities of constitution, of food and employment, or from acquired habits and indulgences; yet there can be no doubt that, when once induced, they modify still further these functions, and thus draw on other lesions, and ultimately still greater alterations of both function and structure, or even speedily fatal disease. But we are not altogether justified in considering these contingencies as the primary causes of the changes now described. We are rather to view them as more or less remote effects of the failure of the vital endowment of the frame, manifesting itself first in a less perfect performance of the different functions, and subsequently in modifications of structure, and ultimately in very obvious lesions of both function and structure.

47. *b.* It was supposed by Brown and others, that the embryo at its earliest formation is endowed with a certain sum or allotment of vitality, which, in the earlier epochs of life, is engaged in the formation of, and in bringing to perfection, the different structures and organs of the frame; that it is gradually exhausting itself ever after, until it at last expires; and that the greater the excitement of its different manifestations and functions during the subsequent stages of existence, the more rapidly will its termination be reached; that the oil with which the lamp of human, and indeed all animal, existence burns, is filled at its commencement, and is never afterwards supplied; and that the more brilliant the flame, the shorter will be its duration. This captivating hypothesis, however, appears, on an intimate view, irreconcilable with many of the phenomena of health and disease. It cannot readily be conceded that the allotment of vitality bestowed upon the germ or germs can exceed that possessed by the parents,—for the hypothesis is, that the sum of vitality is greater the younger the animal; and that it diminishes with the advance of days and years, from the period of its endowing the embryo. But it is obvious, that the greater vital endowment cannot issue from the smaller; that the parents cannot possibly impart to the embryo more than they possess, they still retaining a portion afterwards: more particularly when we consider that the greater endowment is imparted not to one embryo only, but to several, as is the case in the lower animals, and often in the human species also.

48. The phenomena, moreover, of disease furnish us with proofs that this sum of vital endowment is neither thus early and at once bestowed,

nor thus uniformly diminished, according to the waste it experiences, without occasional reinforcement. We frequently perceive all the manifestations of life reduced, at different epochs of existence, nearly to total extinction, particularly in several kinds of fever, when having received the requisite aid from external stimuli, they have been gradually restored to their former activity. Indeed, the various circumstances in which the body is placed, and the different states it presents at different periods of life, and from numerous causes which affect it, seem rather to favour the idea that the sum of vitality, and its manifestations in the different organs, fluctuate more or less during the allotted period of existence; that a certain emanation of vitality proceeds from the parents, great in proportion to their constitutional powers; but that this endowment is constantly experiencing an accession, first from the mother, and subsequently from the common sources of air and aliment; that this reinforcement is thus constantly supplying the waste arising from the exercise of the various functions, and adding to the bulk of the structures, until manhood is reached; and that at this period the sum of vitality has reached its greatest amount, from which it gradually declines, owing rather to the waste, particularly that occasioned by the exercise of the generative functions, exceeding the supply, than from the continued expenditure of what is at first bestowed and never afterwards reinforced.

49. Having been induced by the foregoing, and other considerations, to relinquish the former for the latter hypothesis, I infer that the gradual diminution of the vital energies that accompanies the progress of age is more or less manifested throughout all the frame; that the functions first evince this decline, and that the organs themselves are at last modified in organisation, from the slightest and almost inappreciable shades to the most marked alterations. The changes of structure, once induced, tend most essentially to heighten and to perpetuate the previously slight disorders of function, until both the one and the other undergo, by reciprocity of influence, most important alterations, terminating at last in death, and the dissolution of the frame.—I now proceed briefly to notice those changes of function which, frequently related to the alterations of structure described above, mark the existence of Age.

50. *c.* I have, in another place, stated that, of all the different tissues of the frame, the ganglial system is the most intimately related, in every way, to the vital influence which endows the body. And it is precisely those organs which are most immediately connected with this system that first furnish proofs of incipient decline in the languor or imperfection of their functions. Amongst those functions are comprised those of digestion, secretion, circulation, assimilation, the preservation of the animal temperature, and generation. The functions of animal relation are not so soon affected; and at first the change in them is rather secondary, and owing to the pre-existing change of the functions of organic life,—of those functions which are excited or actuated through the medium of the ganglial system.

51. As very intimately dependent upon the state of the ganglial system, the secretions manifest, with the advance of age, the most remarkable

lesion. These are generally modified in *quantity*, in *fluidity*, and in *quality*. 1st, The quantity of the secretions, both recremental and excrementitious, is sensibly lessened. The salivary, gastric, biliary, cutaneous, and spermatic secretions evince this change. 2d, Their fluidity is diminished, as shown by the salivary, the lachrymal, cutaneous, and watery exhalations and secretions. And, 3d, their properties are modified, as proved by their marked tendency to assume, immediately as they are secreted, irritating and acrimonious qualities, as shown by their effects upon the tissues with which they remain for any time in contact, and to pass rapidly into decomposition. The urine, and occasionally the lachrymal, the mucous, the biliary, cutaneous, and sebaceous secretions evince this change. It very generally happens that the secreted fluids experience more than one of the above alterations; they being diminished both in quantity and in fluidity, and at the same time deteriorated in quality. This is remarkably the case in respect of the cutaneous, mucous, and urinary secretions; the chief exception being furnished by the mucous fluid, which is sometimes increased, although it is of diminished fluidity and altered quality: but this is rather an effect of disease, than merely of advanced age.

52. Next to the function of secretion, and owing to the same cause,—the diminution of vital influence,—that of circulation is most sensibly affected. The action of the heart is slower than in early life, much less energetic, and occasionally irregular. The capillary circulation is more languid, and a much smaller quantity of blood penetrates the extreme ramifications and nutritious vessels, in consequence, most probably, of the diminished calibre of those vessels, and the increased density of the tissues in which they terminate. The venous circulation is more congested, and more prone to experience the consequences of engorgements, particularly varicose dilatations, giving rise to effusions of blood and other serious diseases. The blood itself is not only diminished in quantity, but is also of a darker colour, and is probably also slightly changed in quality, particularly in respect of certain of its saline constituents. The absorbent system is less frequently disturbed in its functions by age than almost any other part of the frame, although it occasionally evinces diminished power, but chiefly in connection with disease. To the predominance of the absorbent function over that of arterial circulation has been partly ascribed, and with apparent justice, the wasting and condensation of the structures characterising the most advanced epochs of life.

53. As intimately connected with the weakened energy of the ganglionic and vascular systems, the functions of digestion and assimilation are languidly performed. The gastric, pancreatic, and biliary juices are less abundantly secreted in the aged than in those of early or mature years; and the tonic contractility of the coats of the stomach and bowels is diminished. Hence result various dyspeptic ailments, flatulence, and a sluggish state of the bowels. The receptacles which nature has provided for the temporary retention of the secretions and excretions, particularly the biliary and urinary bladders, react imperfectly on their contents, owing to the lowered power of the nerves which actuate them: hence arise distention

from the inordinate accumulation of the secretions poured into them, and changes of the properties of these secretions during their retention, either occasioning their expulsion, or producing actual disease.

54. As closely related, also, to the lowered energy of the nerves of organic life, and consequent languor of the circulation, the generation of animal heat in the aged is evidently diminished, although the causes which usually moderate it in the young,—namely, abundant exhalation and evaporation from the surfaces of the lungs and skin,—exist in a much less degree in the former. The functions of generation, are, however, those most remarkably affected. In the female the faculty of conception is altogether abolished, and important changes occur in the state of her appropriate organs; yet the sexual desire still lingers for a while: and in the male, although the ability of procreation may remain, under favourable circumstances, for some time, it is at last entirely abolished.

55. Thus we perceive, that as the different viscera of organic life increase in density, and experience a diminution of vital expansibility and contractility, so their functions become more languid or imperfect, until some of them cease to be performed, and others are remarkably altered. But the change is not limited to this class of structures. Those organs which are devoted to the extension of our intercourse with surrounding nature, and are subservient to the manifestations of mind, as well as those manifestations themselves, in both their intellectual and moral relations, undergo, although at a more advanced period, in respect of some of them, very marked modifications.

56. The changes that take place in the muscular and their associated structures evidently would render them incapable of performing those actions, to which volition may impel them, with energy, rapidity, and steadiness, even although the nervous system of voluntary motion were altogether unaffected. But this system, owing probably to the slight, and nearly unappreciable, alterations noticed above (§ 36), possesses much less energy and susceptibility of action than in the prime of life, and therefore actuates the muscles in a less vigorous manner.

57. The same condition of the brain and cerebro spinal nerves, which contributes to render the actions of volition less precise and energetic, seems also to be connected with the less vigorous exercise of the intellectual powers, and the imperfect conditions of the functions of sense. These functions generally indicate incipient decay before the powers of mind are affected; and some of them are nearly abolished, particularly hearing and seeing, before the latter evince any marked change. But more commonly the decay of the senses is soon followed, occasionally as a necessary result, by a slight failure of some of the mental faculties. The memory, and the power of association as intimately related to memory, are the first to evince this declension, generally by a want of recollection of the names of persons, subsequently of the names of things and of recent events, or recently detailed information; the judgment continuing either altogether or but slightly impaired. With this declining state of the faculties, the emotions of the mind are often remarkably blunted; the desires and affections are

impaired, excepting in as far as respect early-formed associations and affections, which are often recalled with acute and even overwhelming emotion.

58. As age advances sleep is much lessened; and not only is the duration of repose abridged, but also its soundness; the rest of the aged being imperfect, and disturbed by dreams. It is difficult to explain this—indeed no satisfactory explanation of it has yet been offered; but it is generally observed, particularly in very advanced age.

59. Such are the changes induced by age in the various structures and functions of the body, as evidently caused by the gradual decline of the vital energy, from the period of full manhood to its ultimate extinction. I have described them as much divested as possible of the effects of disease. As now noticed, those changes gradually lapse into death,—the lamp of life having burnt out, its oil having been exhausted, after a gradual diminution of the supply, without any single organ evincing that state of disease to which the cessation of life can be ascribed. This is, however, not a common occurrence; for, during the gradual decay that marks the progress of age, some organ or other, owing to the deleterious influence of surrounding agents, or of mental emotions, and the weak resistance of the vital influence, experiences a more or less marked derangement, which increases to actual disease, and either abridges the remaining short period of existence, or renders it less supportable.

I now proceed to notice the different epochs of advanced age, with reference chiefly to the diseases incidental to each, and to the therapeutical considerations which should influence the treatment of them. (See CLIMACTERIC DISEASE.)

60. vi. PERIOD, or DECLINING AGE.—1st Epoch, or *declining age*, extends from 42 or 45 to 55 in the female, and from 48 to 60 in the male.—*a*. During this period the appetites, occupations, and habits express themselves still more strongly upon the outward appearance of the frame than in that immediately preceding it; and the feelings, emotions, disappointments, and anxieties of life manifest more fully their effects upon the internal organs, as well as upon the external aspect. Venous congestions, visceral obstructions and engorgements, with all the specific forms of disease already enumerated (§ 30.), are more frequent than during earlier epochs, particularly apoplexy and paralysis, hæmorrhoids, hepatic disorder, dropsies, structural change in the kidneys and bladder, hypochondriasis, hæmatemesis, gout, and chronic affections of the respiratory organs.

61. *b*. In this period, the second great change to which the constitution of the female is liable generally occurs, terminating that epoch in which her sexual constitution is especially marked; and with this change frequently commence, or are matured, several diseases of the female organs. Morbid changes of the uterus and its appendages, as well as of the breast, are now very frequent; and sometimes they assume a malignant character. Various maladies, to which the female was less exposed than the male, are now oftener met with; and her constitution, with its disposition to disease, approaches more nearly to that of the male than during the time of marked uterine activity.

62. 2d Epoch, or *advanced age*, may be reckoned to commence about 55, and to extend to 63 or 68 for the female; and to begin about 60, and extend to 65 or 70, in the male. During this epoch the nervous, circulating, and muscular energies begin to languish, with the vital actions of the different internal organs. The functions of the sexual organs gradually disappear. The female no longer conceives; and sexual plethora has ceased to supervene and to relieve itself by a periodical discharge. The ovaria begin now to be gradually diminished in bulk, and to assume a firmer structure; the appetite for procreation slowly disappearing (§§ 43. 54.).—The male organs also either become less disposed to their proper functions, or nearly altogether lose the faculty of performing them, particularly when the energies of the constitution have been exhausted by previous indulgences carried to an excessive length, or by mental exertions. The teeth decay, and the digestive functions suffer from the imperfect mastication of the food (§ 41.).

63. vii. PERIOD, or OLD AGE.—1st Epoch, or *ripe old age*, dates from the preceding, and extends to 75 or 80 in both sexes. During this term the sensiferous and sanguiferous systems languish more and more, and all the vital organs experience a rapid decline of activity. The teeth fall out, the gums are partially absorbed, and the digestive functions are greatly impaired. The sexual organs are nearly or altogether deprived of their functions; the digestive and assimilating viscera experience a marked diminution of power; and senile marasmus, or the leanness of old age, advances (§ 53.).

64. *a*. The diseases of this and the preceding epochs are chiefly weak or imperfect digestion and assimilation; chronic inflammations; general asthenia and cachexia; apoplexies; paralysis; loss of the senses of sight and hearing; senile gangrene; comatose affections; dyspnoea; diseases of the heart and liver; dropsies; organic changes in the urinary and sexual organs of both sexes; passive hæmorrhages, from the stomach, bowels, and urinary organs; mental disorder; and gradual extinction of the vital functions and energies. Febrile and inflammatory diseases have a much more marked disposition to terminate in organic change, owing to the diminution of vital resistance, than during the preceding epochs of life.

65. *b*. The therapeutical indications of this period are in some respects important, but chiefly with reference to the necessity of supporting the powers of life during the diseases to which it is liable. When inflammatory or febrile disorder is present, and depletions or evacuations are necessary, we should, particularly if we employ them actively, watch their effects, and resort to the use of means calculated to support the frame as soon as indications of exhaustion are manifested. Purgatives at this period should, if frequently repeated, always be combined with warm, tonic, or supporting medicines, or with a restorative regimen; and a strict reference ought to be made to the habits, constitutional powers, and feelings of the patient, in all the remedies we prescribe. Old habits must not be suddenly relinquished or opposed, and the powers of life should be carefully watched; for, if unheedingly reduced, they will, particularly in large cities, often sink most rapidly, without the power of rallying. When we

consider that, in persons advanced to this age, a considerable portion of the arterial system is often in a state of slow organic disease; that the venous system is prone to congestion, is sometimes relaxed and almost varicose, always deficient in vital contractility, and scarcely able to perform its functions; and that both the one and the other cannot thereby so readily accommodate themselves to sudden or copious losses of blood as in early life and when they are perfectly free from disease, we cannot be surprised at the sudden depression occasioned by vascular depletion, or other means which produce a rapid discharge by the emunctories of the watery parts of the blood, or a sudden depression of the nervous energy, even although symptoms seemed unequivocally to demand their employment.

66. The *last epoch*, or that of *Decrepitude*, or *second infancy*, commences at from 75 to 85, and terminates the life of those whose span of existence is thus far prolonged. A greater number of females than of males reach this extreme age, especially the utmost extreme. During this period, all the physical and mental powers rapidly decline. The body emaciates, the muscles waste, and the adipose structure is absorbed; the integuments becoming lax, wrinkled, dry, and disposed to retain accumulations of sordes. The knees totter and bend under the weight of the body; the trunk stoops, and is incapable of any considerable motion, excepting forwards; and the features are wan, devoid of colour, wrinkled, and emaciated, and apparently consisting chiefly of integumental covering (§ 33.).

67. *a.* Congestions, enlargements, obstructions, and even atrophy of the internal viscera; effusions of fluid into the shut cavities; irregularity of the heart's action from loss of its vital activity, or structural change of its valves, its arteries, or muscular texture, or from disproportion between the capacities of its compartments; lesions of the vascular system generally, in which either those of the arteries or of the veins predominate. Passive hæmorrhages from the mucous surfaces, particularly those of the alimentary canal and urinary apparatus; general asthenia, or cachexia; and slow extinction of the vital and natural functions of the frame,—the ganglial, the cerebro-spinal, and the circulating systems; and the digestive, the respiratory, the secreting, and excreting organs, evincing individually, or either of them conjointly with others, more or less disease,—are the principal causes of death: and thus man, whose mental and physical constitution and organisation were objects of profound study and admiration to himself, passes away; the vital essence, that actuated the wisely devised frame with which it was so surprisingly associated, returning to the Divine source whence it emanated; and the gross materials, which it combined and preserved in wonderful states of association, assuming novel modes of existence, and serving to form new beings much lower in the scale of organised creation.

68. *b.* The rapidity with which acute disease generally runs its course at this period, and the celerity with which organic change will frequently supervene and extinguish the dimly burning taper of life, require great decision and circumspection on the part of the physician. The resistance which the energies of life usually oppose both to the extension of disease to Æther viscera from that

first attacked, and to its disorganising effects in its primary seat, is now so excessively weakened, that remedies, directed with a due regard to the previous habits of the patient, in support of those energies, are particularly necessary. On the choice of cordial remedies, and on their appropriate application to the circumstances of individual cases, will depend their success, and the reputation of the physician. At this period, depletions and all evacuations, excepting such as are requisite to carry off accumulations of morbid matters from the *primæ viæ*, and which impart, along with their evacuating operation, a restorative and cordial influence, must be abstained from; and care should be taken that fainting, or even nervous depression, may not supervene from their action. Warmth, at this and the preceding terms of advanced age, is indispensably required, both in the clothing and apartments; but it should be equable, and not too high. The lungs of very aged persons should be guarded from the ingress of very cold air, as the impression of cold in this organ paralyses its functions, arrests those changes which the blood undergoes during respiration, and induces apoplectic or comatose seizures, and idiopathic syncope or inaction of the heart. For these reasons, also, atmospherical vicissitudes should be assiduously avoided, as far as the means of doing so are placed within our reach. There is scarcely any measure more influential in supporting the sinking vital energies of age than the communication of animal warmth, particularly from the young of our own species. This was well known to the ancients, and is one of the oldest restorative means of treatment practised, having been adopted by DAVID. The aged ought also to avoid the use of very cold fluids, as being apt to depress the energy of the stomach below the power of healthy re-action. Medicines, also, particularly purgatives of a cold nature, as the neutral salts, if exhibited at all, require to be combined with warm aromatics or stimulants, in order to counteract their depressing influence upon the alimentary canal, and on the nerves of organic life.

AMAUROSIS, from *ἀμαυρός*, obscure. SYN. *Gutta Serena*, *Suffusio Nigra*, Celsus, Lucretius, Pliny. *Obscuritas*, *Hebetudo*, Paulus Aegin. *Paropsis Amaurosis*, Godd. *Cataracta Nigra*, Auct. Germ. quibusd. *L'Amaurose*, Fr. *Die Schwarze Staar*, Germ. *Gotta Serena*, Ital. *Stekelindheit*, Hol. *Suffusio*, *Drop Serene*, Milton. *Dimness of Sight*, *Blindness*.

CLASSIF. 4. *Class, Local Diseases*; 1. *Order, Impaired Sensations (Cullen)*. 4. *Class, Diseases of the Nervous Function*; 2. *Order, Affecting the Sensations (Good)*. *Functional Amaurosis*, 1. CLASS, IV. ORDER, *Organic Amaurosis*, IV. CLASS, III. ORDER (*Author, see the Preface*).

1. DEFIN. *Partial or total blindness, from affection of the retina, or of the nerves, or of that part of the brain related to the organ of sight, whether arising primarily from functional disorder, congestion, inflammation, or any other change of these parts; or occurring from sympathy with other organs.* Or, in other words, *Partial or total loss of sight, from other causes than those which obstruct the passage of the rays of light to the bottom of the eye.*

2. Amaurosis is met with at all ages; but most frequently in the more advanced terms of life. It is sometimes congenital; and in these cases it is often difficult to ascertain the nature and seat of the affection. When it occurs at advanced periods of life, an attentive inquiry into the history of the disease, of the previous habits and ailments of the patient, and of the various resulting and related morbid phenomena, will generally throw light upon its pathology.

3. I. SEAT OF AMAUROSIS.—1st, *In the retina.*—Viewing the delicate structure of the retina; its relation to the optic nerve, of which it is an expansion of great tenuity; its connection with the choroid and hyaloid membrane, and its nervous and vascular communications; and considering the various morbid states it is liable to undergo, in consequence of its relations with these and other parts; a partial, and even total, abolition of its functions is to be looked for on some occasions. It is, like all other parts of the frame, liable to congestion and inflammation, with their usual results; and, like other nervous parts, its functions are subject to a partial or complete extinction without itself evincing any change of structure, its sensibility alone being impaired or abolished; owing either to some unappreciable change, or to some one or more of those alterations in its adjoining or related parts about to be noticed.

4. 2d, *In the optic nerves.*—These nerves may be more or less changed in some part of their course, from the anterior pair of the corpora quadrigemina, along the thalami, the tubera cinerea, and their partial decussation, until they terminate in the formation of the retina. In appreciating, however, lesions in the course of the optic nerves, the results of experiments on them should be taken into consideration:—if an optic nerve be divided previous to this decussation, sight is altogether lost on the opposite side; but if the division be made between the decussation and the eye, vision is lost on the same side.

5. 3d, *In the ganglial nerves.*—There is every reason to suppose that the retina is in intimate communication with other nerves, and that it mutually influences and is influenced by them. Branches of the great sympathetic may be traced upwards, from the first cervical ganglion, to the ganglion lodged in the cavernous sinus; whence branches proceed and communicate with the third, the first division of the fifth, and sixth pairs of nerves. Branches also pass from the cavernous ganglion directly to the lenticular ganglion. As the internal carotid artery passes into the cranium, it is surrounded by the sympathetic nerves, which accompany all its ramifications. The ophthalmic artery is invested with these nerves; its branches to the choroid, iris, and retina being similarly provided. Branches of nerves, moreover, proceed from the lenticular ganglion, as M. RIBES (*Mém de la Soc. Méd. d'Emulation*, t. vii. p. 99.), and others have demonstrated, to the iris, giving more minute branches in their course to the retina. This connection being established, morbid states of these nerves and ganglia, or changes of structure in their vicinity affecting their functions, must necessarily impair the sense of sight.

6. 4th, *Other nerves*, as the fifth and third pair are, in some cases, also the seat of amaurosis. It has been shown by MAGENDIE and DESMOULINS that the integrity of the fifth pair is necessary to the perfect function of the retina; and Mr. MAYO has furnished evidence that the third pair is requisite to the motions of the pupil. If the great sympathetic be divided in the upper part of the neck, the pupil becomes contracted and immovable, and the eye wastes.

7. 5th, *Parts of the encephalon* connected with the optic nerves in their course are occasionally the seat of amaurosis, as pathological research and experiment have shown. MM. MAGENDIE and SERRES have proved that, when these parts are wounded, the sight of the opposite eye becomes either weak or extinct.

8. 6th, The *pineal and pituitary glands* are frequently the only parts in which any alteration can be detected in the examination of amaurotic subjects. The connection of these glands with the ganglial system is stated at another place. Besides these, other parts of the brain, when the seat of organic disease, are not infrequently the principal source of amaurosis, as shown hereafter.

9. II. CAUSES.—1st, The *predisposing causes* of amaurosis are very diversified. Amongst these, the influence of hereditary disposition is well established. BEER traced it in several families; in one of them through three successive generations, and particularly in the females of that family who had not borne children, it having appeared in them at the cessation of the menses. BEER also states, that dark eyes are much more liable to it than the light; the proportion being upwards of twenty to one.

10. Whatever tends to favour sanguineous congestion of, or serious effusion in, the encephalon, particularly insolation; forced exertions of the mind or body; excesses of passion; the pregnant and puerperal states; occupations requiring frequent stooping; errors of diet, and neglected ailments affecting the stomach and liver; the abuse of wine or spirituous liquors; suppressed discharges, particularly those from the nose and ears; interruption or entire cessation, of the

menses; the gouty, rheumatic, and strumous diathesis; the retrocession or suppression of eruptive diseases; and habitual constipation; — whatever exhausts the vital energy of the brain, and nerves supplying the organ, as chronic diarrhoea, typhoid fevers, the excessive use of snuff, long-continued grief, prolonged suckling, neglected fluor albus, excessive venery, and manustription; — and lastly, whatever exhausts slowly the sensibility of the organs of sight themselves; as the incautious use of the eyes in a glaring light or on minute objects, and the existence of strumous ophthalmia in childhood, generally predispose to amaurosis.

11. 2d, The *exciting causes* are very numerous; indeed, any of the causes enumerated as merely predisposing to the affection may excite it, when acting long or intensely, although the successive or combined action of various causes are generally required. Amongst the most common exciting causes, are over-exertion of the sight; exposure to very bright light; its occupation on minute objects, or employment in candle or lamp light, and during the hours usually devoted to sleep. The sensibility of the retina may be destroyed, even by a single exposure to these causes. Lightning is another cause, which seems to act by extinguishing the sensibility of this very delicate part. In general, however, it is the long-continued over-excitement of the organs of sight that occasions the gradual abolition of their functions. Injuries on the eye, and in its vicinity, are also frequent causes of the disease.

12. Poisonous substances occasionally produce an attack of amaurosis; sometimes suddenly, at other times slowly. Belladonna, stramonium, solanum dulcamara, &c., fish-poison, various fungi, and animal poisons, occasionally have the former effect; but it is most frequently only of temporary duration; whilst other narcotics taken habitually, as opium and tobacco, produce the latter effect, and in a more permanent manner. The poison of lead, blows on the head, child-labour, and puerperal convulsion, frequent attacks of epileptic or other convulsions, cerebral apoplexies and paralysis, injuries of the branches of the fifth pair of nerves (three cases of which have come before me), and even irritation of these nerves, will produce this affection; it has also been observed to supervene to gastric and intestinal irritation, particularly when occasioned by worms; to hypochondriasis, and accumulations of bile in the liver, &c.; to frights, and to the irritation proceeding from carious teeth. The sudden suppression of epistaxis, of hæmorrhoids, of the lochia, of the milk in nurses, of the menses, or of the perspiration; the repulsion of eruptions on the head and behind the ears, and the drying up of old ulcers, have, severally, occasioned the disease. But most frequently it is the result of two or more of these causes, acting under circumstances of predisposition. Females with dark eyes are extremely liable to the disease, upon the cessation of the menses; and, like deafness, it is apt to appear after severe attacks of typhoid and scarlet fevers. Amongst the more rare exciting causes of this affection, are the gouty and rheumatic diathesis, or misplaced and retrocedent gout and rheumatism; the constitutional effects of syphilis, and hurtful influence of mercurial courses; — all which have been assigned

as causes of the disease by some authors, and denied by others; but, undoubtedly, producing it on some occasions, although not so frequently as the former believe.

13. 3d, The *proximate or efficient causes* of this affection are various. It has been disputed whether or not it can arise from altered function only, and without change of structure. Mr. TRAVERS believes that it does, but Mr. MACKENZIE denies it can depend upon morbid function merely; and other writers take opposite sides of the question. There can, however, be no doubt, if we attentively consider the disease in relation to the exciting causes and the effects which are observed to result from them, that, although most commonly the consequence of some appreciable change in some one or more of those parts instanced as its seat (§ 3—6.), it is occasionally unattended with such change, — at least to such an extent as our observation of the effects proceeding from similar alterations would lead us to expect. It should not be overlooked that the operation of many of the causes which have been adduced above is entirely vital — upon the functions of life, as manifested in the organ, or in remote parts of the frame; — that their effects are sometimes almost instant, and before organic change could have been produced; and that the disappearance of their effects has been sometimes as sudden, and often before the restoration of morbid structure, providing that it existed, could have been brought about. I believe, after a careful perusal of the works which have been furnished by surgeons on this disease, that a too marked disposition has been evinced to consider it as a result of organic change in the organ and the nerves, and vessels connected with it, and without relation to constitutional and vital causes.

14. When describing the *seat* of amaurosis, the influence of organic changes has been briefly noticed; and a fuller reference to them will be made in the sequel. Amongst the numerous lesions of structure that occur in the brain and its membranes, there are many that affect the nerves of sight, more particularly the optic nerves, or which implicate them organically in some part of their course in a very remarkable manner. Alterations in the bones of the cranium, as well in the membranes, obstructing the functions either of these nerves or of the other nerves subservient to the perfect exercise of this important sense, are also not uncommon.

15. The *EFFICIENT CAUSES* of this affection, therefore, are, 1st, *vital or functional*, depending upon imperfect or abolished sensibility of the retina, or of the optic and other nerves subservient to vision, owing either to causes which, from their direct and local action, depress or exhaust this property, or to those which, from their primary influence upon the frame, have an indirect depressing effect, which is not limited to this organ, although manifested in it in a more marked degree, owing to various concurrent circumstances. This constitutes the *functional form* of amaurosis admitted by BEER, WARDROP, TRAVERS, SANSON, and others, and which BEER divides into two subordinate kinds: *first*, that which proceeds from direct depression of the vital sensibility of the eye; and, *second*, that which is owing to inordinate excitement, and consequent exhaustion of this property.

16. 2d, *A congestive or inflammatory state of the vessels of the retina, or parts immediately adjoining, or the usual effects of these states.* — PORTAL, PLOUQUET, PROCHASKA, ROUSSEAU, SANSON, MAGENDIE, and other pathologists, have observed varicose states of these vessels; unusual injection of the minute arteries of the adjoining coats, and of the retina itself; a complete *retinitis*; exudations of lymph under the choroid, near the ciliary circle; inflammation of the external surface of the sclerotic; vascular injection, and firm adhesion of the retina to the choroid; partial detachment of the retina from this coat; and thickening, morbid density, and change of colour of the retina. Ossification; fibrous degeneration, with partial thickening; wasting, and malignant disease of the retina, and even the development of transparent vesicles in it, have all been noticed by HALLER, MORGAGNI, HEISTER, SANSON, and other authors.

17. 3d, *Lesions affecting the optic nerves.* — These consist chiefly of tumours of various kinds — osseous, fibrous, encysted, steatomatous, puriform, aneurismal, &c. — formed in their vicinity, either in the brain, the membranes, or in the bones of the cranium, and involving, or compressing them, in any part of their course. They are likewise, occasionally, the seat of some one, or even more, of those organic changes of their proper structure and sheaths, to which nervous parts are liable. Their vessels may be varicose; their fibres may be infiltrated with serum; they may be injured by external violence, and they may be wasted; which last is very frequently observed. Adventitious deposits, as osseous and earthy matter, malignant formations, cysts and hydatids, may even form in their sheaths, although more rarely than the foregoing lesions. The writings of pathologists abound with instances of these changes. When only one eye has been amaurotic, the optic nerve of that side has been found wasted anterior to its partial decussation; and on the opposite side, posterior to this union. But this is by no means an uniform circumstance, and, when observed, the atrophy is not distinctly continuous. Indeed, the wasting has been detected on the same side, after the union of these nerves, as well as before. But if the opinion of TREVIRANUS and WOLLASTON be correct, — that decussation of these nerves at their union is only partial, and that it takes place chiefly between the parts which are nearest each other, — wasting of one of them may be in one case more remarkable on the same side, and in another case more observable on the opposite side. When the amaurosis is accompanied with wasting of the optic nerve, from causes not primarily consisting of inflammation or its consequences in the retina or adjoining coats, this nervous expansion is also generally wasted, transparent, or changed in colour. When the cause exists in the pineal or pituitary glands, the wasting is often chiefly observable at the union of the optic nerves. In these cases, both eyes are affected. Facts illustrative of this have been recorded by VIRSSENS, DE HAËN, RULLIER, RAYER, WARD, and SANSON.

18. 4th, *Lesions seated in the encephalon.* — The scope of this article will not admit of further reference to the numerous changes which occasionally produce amaurosis, from their affecting

the optic nerves in their different connections with various parts of the encephalon. All the alterations which are described in the articles on *morbid structures of the brain and its membranes*, will produce the disease, when they impede the functions of the optic nerves, although the structure of these nerves may be uninjured. The most frequent and remarkable of these are, organic lesions of the pineal and pituitary glands (§ 8.), sanguineous and serous effusions, various kinds of tumours, abscesses, softening of the brain, &c.

19. 5th, *Lesions of nerves subsidiary to the integrity of the organ and of its functions.* — Injuries, compression, and even irritation of the fifth pair of nerves, particularly its ophthalmic branch, of the third and sixth pairs, and of the ganglia or their ramifications, by organic change in the brain, its membranes, bones of the cranium, or parts in the course of their branches, have been shown, in numerous instances, to have been the chief efficient causes of amaurosis.

20. III. SYMPTOMS.—The symptoms of amaurosis are, 1st, those which the *patient himself experiences*; and 2d, those which the *physician detects* in the eyes, or in the various organic and animal functions. Each of these classes of symptoms are to be inquired into separately, commencing with either of them. Each eye should be carefully and separately examined; and it will be better that the other is excluded from the light, whilst the examination is being made.

21. 1st, The patient complains of impaired vision, which may be of gradual accession, or remarkably sudden, and amounting to almost total deprivation of sight. Hence the disease has been distinguished by the epithets *slow and sudden, incomplete and complete, or imperfect and perfect*.

22. At the commencement, the failure of vision is sometimes only occasional, for a short time, and after longer or shorter intervals (*amaurosis vaga*). In some cases it assumes the form of *day-blindness*, in others of *night-blindness*: and it not infrequently recurs for a time after great exertion of the eyes, either with minute or bright objects. Transient and sudden attacks of the disease are often the consequence of disorder of the digestive organs, or rather the result of a state of the vital manifestations which occasions equally loss of sight as well as loss of the digestive functions. The failure of sight is often at first only partial — extending only to a part of the field of vision. In some cases, intervening portions of the field are obscured (*visus interruptus*). In other cases, one half of it is hid from view (*hemipopia*). Occasionally objects are only seen in a particular direction (*visus obliquus*); and some patients discern objects in a distorted form — crooked, mutilated, shortened, lengthened, or inverted (*visus defiguratus*). BEER states that the flame of a candle will often appear elongated, and as if separated into several portions, to such patients, — a symptom indicating disease within the head.

23. In some instances the failure of sight assumes a *myopic* or a *presbyopic* form: but this is not so frequent as the occurrence of false impressions, in the form either of flashes of light, shining stars, globes of light, and various other lucid spectra (*photopsia*), or of *musca volitantes*. False impressions of colour (*chropsia*) are also frequent attendants on the early stages of amaurosis. Luminous spectra are commonly met with in plethoric

persons, and when the amaurosis depends upon increased vascularity, or inflammation of the retina; motes, black specks, muscæ volitantes, and thick mists or clouds, when the affection is dependent upon exhaustion of the sensibility and vital energy of the organ, and when it occurs in dyspeptic subjects from exhausting causes. Double vision is also a common symptom, particularly when the cause exists within the head.

24. As the disease advances, the field of vision appears as if obscured by a cloud, or net-work; the latter appearing grey or black in a good light, but occasionally becoming white, silvery, yellowish red, and luminous in the dark. In addition to these, the patient sometimes complains, particularly early in the disease, of some intolerance of light, or of pain in the eyes on being exposed to it. But, in other cases, from the very beginning, diminished sensibility of the retina, and a constant desire for a stronger light—a thirst of light—are present.

25. Pain in the eyes, and commonly also in the head, is one of the most important symptoms of amaurosis. It should, therefore, be carefully investigated. We ought to ascertain its precise seat and extent; its character—whether it be acute, gravative, throbbing, occasional, or permanent. The circumstances which relieve or exasperate it should also be noted; as the horizontal posture, temperature, exercise, diet, the use of stimuli, &c. We should also notice whether it be accompanied with vertigo, tinnitus aurium, watchfulness, or stupor, coma, forgetfulness, inability of exertion, or failure of other mental manifestations; as, from the nature and grouping of these symptoms, we infer the nature of the efficient cause of the disease, particularly as they suggest its existence within the cranium.

26. Unusual dryness of the eyes and nostrils sometimes is observed in amaurosis; and in these cases benefit is often derived from a restoration of the secretions of the lachrymal gland, conjunctiva, and Schneiderian membrane. (MACKENZIE.)

27. The general health, and previous ailments of the patient require a particular investigation. The constitution and diathesis—whether he be strumous or gouty; whether he has had syphilis, or undergone long courses of mercury; whether he has had typhoid fevers, or inflammations of the brain, or apoplexy, paralysis, epilepsy, or injuries on the head; whether he has been subject to complaints of the digestive organs, or has been, or is, affected with worms: if a female, whether she has been frequently attacked with paroxysms of hysteria, or any of its anomalous forms, or with convulsions in the puerperal state, and particularly whether or no there exist any sign of disorder in the uterine organs—are all particulars most requisite to be known.

28. 2d, The form, colour, vascularity, and mobility of the different parts of the eye, and habit and appearance of the patient, next require investigation. The amaurotic patient walks with a gait of uncertainty, and a staring and unmeaning look. In some cases this want of convergency of the eyes towards an object may amount to slight squinting, occasionally with oscillation, and sometimes with unusual fixity of the eyes. In some instances, the motions of the eyelids, and of the eyes themselves, are more or less impeded, or even palsied,—the levator palpebræ superioris, and the orbicu-

laris palpebrarum being often affected. These phenomena are chiefly remarked in cases where the motor oculi, or the facial nerve, is injured.

29. One or both eyes are often unusually prominent. The colour of the sclerotica is frequently somewhat changed—being either yellowish, bluish, or ash-coloured. This coat is often covered with small varicose veins. The consistence, also, of amaurotic eyes is occasionally altered; in some cases the eyeball is firmer to the touch, in others softer, than natural. In rarer instances, it is flattened on one or more of its sides.

30. The pupil is generally sluggish and limited in its motions, or altogether deprived of motion, and dilated. More rarely it is contracted. In many cases it is neither dilated nor contracted. A widely dilated pupil, although generally attendant on pressure on the brain, also occasionally depends on other causes. Early or incomplete amaurosis is rarely attended with dilated pupil; but after all vision is extinct, the pupil is generally more or less expanded and motionless. It should not be overlooked, that where only one eye is amaurotic, the motions of the pupil of the affected organ will often follow those of the sound one, when protected from, or exposed to, light; and even, as observed by JANIN, both eyes may be completely amaurotic, and yet both pupils will vary in diameter with the intensity of light to which they are exposed. This phenomenon can only be explained by referring to the nerves supplying the different parts of the organ. The iris, being chiefly supplied with ganglial nerves, will often retain its faculty of motion, when the efficient cause of the disease affects the optic nerves at any place between their origin and their communication with the third pair; or when the affection of the optic nerves within the cranium does not leave the retina altogether deprived of sensibility, although the impression cannot be conveyed to the brain, the subsidiary nerves, particularly the third and fifth pairs, and the branches from the cavernous and lenticular ganglions, still bestowing sufficient sensibility and mobility on the iris to admit of motion on being stimulated.

31. Besides the size of the pupil, it is necessary to attend to the characters of the motions of the iris. This part may contract on one side, or in one part, drawing the pupil to one side, or giving it an irregular appearance. It may also seem as protruded towards the cornea, or it may appear sunk inwards, and have a funnel-like shape. (MACKENZIE.)

32. The appearance of the humours of the eye is also important. In hydrocephalus, or when occurring in young subjects, the pupil has the natural black hue. But in elderly subjects some degree of glaucoma accompanies amaurosis. This appearance is in general unfavourable.

33. The presence of the marks of injuries about the face and head is important, as marking probable injury of parts within the cranium, or of some nerves subservient to the perfect condition of the organ. The character of the countenance, the shape of the head, the state of the vessels of the head and eyes, and the general habit of body, require to be noticed. The inference which ought to be drawn as to the exact nature of the disease will be very different when it is met with in the plethoric, the highly fed, and the indolent, from that which will be deduced from its occurrence in

the emaciated or exhausted subject. The probable predisposing and exciting causes should also be investigated, as they have an obvious relation to their effects. Attention should be directed to the previous habits, indulgences, ailments, occupations, and modes of life of the patient &c., with the view of throwing light upon the causes and pathological relations of the malady.

34. The duration of the disease is extremely various. It may, in slighter cases, be only of a few hours' or days' continuance; may altogether disappear, either spontaneously or from treatment, and never afterwards recur; or it may return after an indefinite period, from errors in diet, disorders of the digestive organs, or from the operation of the causes usually producing the disease. It very frequently continues all the life of the patient.

35. IV. STAGES, GRADES, AND FORMS. — The stages of amaurosis are *incipient* and *confirmed*. In the former the sight is generally not altogether lost, although more or less impaired. Treatment will often retard or check the progress of the disease, and sometimes even bring about a perfect cure. But the blindness may be complete from the first: in this case, medicines are generally without effect. In the *confirmed* stage, the disease is usually stationary; but the sight is not always altogether lost: the patient often retaining a perception of light and shadow, or even of objects, when illuminated or strongly contrasted. When this power of distinguishing any object or colour is still retained, even in the slightest degree, the amaurosis is said to be *incomplete*. When the patient is insensible even to the presence of light, the disease is *complete*. It may be limited to one eye, in the incipient or incomplete states; or it may affect both equally, either in an incomplete or complete form. It may also be incipient in one eye, and confirmed in the other; and it may be more or less complete in either. It may likewise, in one or other of these states or forms, assume a *recurrent* or *remittent* type; but such cases are comparatively rare.

36. But, besides these stages and grades of the disease, other forms occasionally present themselves, which will be more fully noticed in the sequel. It may be *Idiopathic*, depending upon changes, either *functional* or *organic*, taking place primarily in the nervous apparatus of the eye, and existing *simply*, and without any other associated lesion; or it may be *complicated* with lesions of adjoining parts, or with other diseases of the eye, particularly of its humours, more especially with glaucoma and cataract. It may also be *consecutive* of other diseases; most frequently of organic changes within the head, or in the vicinity of the orbit, as in apoplexy, paralysis, &c. And, lastly, it may be *symptomatic* of, or supervening to, pre-existent disease of distant parts, particularly of the abdominal viscera; or it may be occasioned by pregnancy, and more rarely by diseases of the puerperal state. It is not infrequently thus symptomatic of colic from lead, accumulations of faecal matters in the large bowels, hypochondriasis, &c.

37. According to these states of the disease, its different species will next be considered, and the treatment which is appropriate to each of them will subsequently be pointed out: for it is obvious, that the success of remedies will, in this very difficult and variously complicated disease, mainly depend upon the strict appropriation of remedies to its different varieties and states.

38. *Spec. 1st, Functional Amaurosis.* — This form of the disease generally arises, — 1st, from suspension or exhaustion of nervous and sensorial power; from various local and constitutional causes (§ 13.); from inordinate excitement or exertion of the visual organs; from mental exertion, watchfulness, and sedentary habits; from the deleterious action of mineral, vegetable, and animal poisons, as lead, mercury, narcotics, &c.: 2d, from venereal indulgences; excessive secretions and evacuations; depression of the vital energies from diseases of debility and exhaustion: and, 3d, from temporary diminution of the local circulation; from simple congestion, or occasional determination of blood in the veins or arteries; and from the irritation or disturbance of the digestive organs, or of some other of the abdominal viscera.

39. The symptoms of this species are, chiefly, more or less obscuration of vision, occurring slowly or suddenly, the visus nebulosus, and muscae volitantes; a somewhat contracted pupil, and clear state of the humours; equal imperfection of sight in both eyes; pale, languid countenance, and depression of the eyes in the orbits; a languid, small, or weak pulse; increased dimness, or sudden abolition of sight upon quickly assuming the erect, from the horizontal posture. An improved state of the sight after a light meal, or grateful stimulus; nervous headaches; weak digestion, sluggish state of the bowels, flatulency, foul or loaded tongue, and indisposition for, as well as incapability of, physical or mental exertion or occupation; weakness in the joints; occasionally nocturnal emissions, &c. in the male, and leucorrhœa in the female.

40. This species of amaurosis may be, 1st, *Primary* and *uncomplicated*. — In this case it usually proceeds from causes which depress or exhaust the sensibility of the retina and its related nerves. 2d, It may likewise be *consecutive*; particularly of excessive secretions and discharges from the uterus, mammae, kidneys, testes, and prostate; or from exhausting and debilitating diseases, as adynamic diseases, hæmorrhages, &c. 3d, *Symptomatic* of, or *complicated* with, hysteria, hypochondriasis, colica pictorium, diminished vital energy of the digestive organs, and all the various forms of indigestion; the presence of worms in the bowels; pregnancy; obstruction and accumulation of bile in the bile-ducts or bladder, &c.: and, 4th, *Metastatic*, or supervening upon impeded or checked secretions and discharges; in which cases it is generally accompanied with congestion, or determination of blood to the head, in which the eyes may partake, but not to an extent constituting inflammatory action or organic change; and it assumes a state nearly approaching to that characterising the next species.

41. *Spec. 2d, Amaurosis from active congestion.* — The existence of this species of the disease is more a matter of inference, than almost any other of those in which I have divided the disease. Yet it seems undoubtedly to exist; especially when amaurosis is consequent upon obstructed secretions and discharges, or the drying up of eruptions; upon frequent stooping, or wearing a tight neckcloth; upon fits of passion, when it occurs in plethoric persons; and after narcotic poisons.

42. The symptoms indicating it, are throbbing in the eyes, tinnitus aurium, turgescence of the vessels of the scleroticæ and conjunctiva, a somn-

what contracted pupil, and clear state of the humours; turgescence of the features, or lividity or bloatedness of the face; fullness of the jugular veins, prominence of the eyes, and impeded circulation through the lungs or cavities of the heart.

43. This form of the disease is seldom *primary* and *uncomplicated*. It is commonly *consecutive*, or *symptomatic*, generally of obstructed discharges, &c. (§ 12.) of disease within the head, particularly of sanguineous congestions, or effusions, and diseases of the lungs and heart. It not infrequently occurs transitorily from pregnancy, epilepsy, and hysteria; and more rarely from gout and rheumatism.

44. *Spec. 3d, Amaurosis from inflammation of the retina, and internal parts of the eye.*—In stating amaurosis to be often a symptom merely of retinitis, I am supported by the opinions of many of the best British and Continental writers on the disease. But I believe it very seldom occurs, that the inflammation is limited to this membrane, but that the choroid and iris generally participate with it in the morbid action; and that, when they, on the other hand, are thus affected, the retina is also inflamed. Amaurosis is therefore a consequence of inflammation of the internal structures of the eye: but does inflammation of these parts uniformly produce amaurosis? It is not always consecutive of iritis; and I believe that the retina may be inflamed, and yet but very slight amaurotic symptoms may be occasioned thereby, particularly during the early stages of the retinitis. It is chiefly when the inflammatory action has produced some degree of organic lesion of the affected parts, that amaurosis is manifested.

45. This form of amaurosis generally proceeds from nearly the same causes as the foregoing (§ 10—12.). It may be produced by syphilis, mercury, eruptive and continued fevers, cold in any form acting upon the eyes or face; suppressed discharges, or eruptions on the head or behind the ears; injuries of the eye and adjoining parts; concussions, and the usual causes of inflammation in other parts.

46. The *symptoms* vary with the extent and intensity of the inflammation. In its slighter states, the progress of the disease, and of the symptoms, is insidious and slow. In these cases, little or no pain is complained of, either in the eye or in the head. The pupil is more commonly contracted than dilated, and the spectra are usually luminous, but sometimes not very sensibly so. With this slight and often chronic state of inflammatory action, the amaurosis may be increasing fast, and the observation of vision very great, and yet the symptoms may not be distinctive; if we except the appearances furnished by the sclerotic, which, in retinitis, as well as in iritis, abounds in red vessels, converging in distinct lines, and forming, by their delicate reticulations, a red zone round the cornea, and which thus furnishes the only symptom, that can be depended upon, of slight or incipient retinitis.

47. In the more intense states of inflammation of the internal parts of the eye, the amaurosis is attended with painful vision; intolerance of light; sparks of fire, or drops of a red colour falling from the eyes; flashes of light; pain darting through the head, either from, or to the bottom of the eyeballs; the pupils are dilated, and the humours

thick or muddy; and there are more or less acceleration of pulse and constitutional disturbance.

48. This species of amaurosis is often *primary*, or *idiopathic*; it may also be *simple* or *complicated*. When it occurs in a complicated form, it is, most frequently, associated with iritis, with meningitis, with eruptive or continued fevers, and with rheumatism, gout, or syphilis. It may also occur *consecutively*, and from *metastasis*, particularly after the disappearance of exanthematous eruptions, as in the measles, small-pox, erysipelas; of chronic eruptions; and after the suppression of habitual or periodical discharges, secretions, and evacuations (§ 12.).

49. *Spec. 4th, Amaurosis from advanced disorganisation of the retina and adjoining parts.*—Disorganisation of these parts is usually a result of inflammation. But it is difficult to determine at what stage of the inflammation organic change commences. I am to consider it here as far advanced; yet, the inflammation that occasioned it may be still present. The *causes* of this species are the same as those of the foregoing; but the *symptoms* are somewhat different. The vision is more obscured. A film seems interposed between the eye and field of vision. The pupil is sluggish, and it is often scarcely dilated; it is frequently irregular. The margin of the iris sometimes partly adheres to the capsule of the lens. The sclerotic is often very vascular, and even livid, from the enlarged and loaded state of its veins, which are very numerous and tortuous. The shape of the eye is sometimes changed, particularly in the most advanced cases; it is prominent in some parts, and depressed in others. The eyeball is occasionally, also, softer or firmer than natural.

50. This form of amaurosis is always *consecutive* of the *second* and *third* species, more particularly of the latter; and hence, participates in many of their characters (§ 41—48.), and occurs under many of the same circumstances as they. It is occasionally *complicated* with cataract, with opacities of the cornea, or with disorganisation of parts within the head.

51. *Spec. 5th, Amaurosis from external injuries of the eyes.*—A blow on the eyeball will not infrequently occasion blindness, without producing any apparent injury of its visible parts. It is difficult, or altogether impossible, to ascertain the nature of the mischief that has been inflicted. The concussion of the organ, and the lesion of the sensibility of the retina and optic nerve, may, in some of the cases, particularly when the consequent amaurosis is merely temporary, constitute the principal or only change. In more permanent and severe instances, it is very probable that the delicate connections of the retina with the adjoining parts are injured. Ecchymosis may also be occasioned, or inflammation may supervene. In these cases the pupil is either dilated, or of an irregular form; and according to the extent of injury will the phenomena partake of the characters which have been assigned to the *third* and *fourth* species of the disease.

52. *Spec. 6th, Amaurosis from disease within the head affecting the functions of the optic nerve, or other nerves subservient to the sense of sight.*—It is obvious that disease within the cranium, either of the substance of the brain, or of its membranes,

producing pressure of, or interrupted circulation in, the parts with which the optic nerve is connected at its origin, or during its course, or acting in a similar manner on the nerve itself, will produce amaurosis. In these cases it is a *consecutive* affection — a symptom merely of disease, often existing for a long time previously. I have already alluded to the nature of these lesions, and to their extreme diversity (§ 17, 18.). Perhaps the most common and the most interesting of them are organic changes of the pituitary and pineal glands, hæmorrhage, sanguineous congestion, aneurismal and other tumours, &c. In these cases it is very common to find cerebral symptoms complained of long before the sight is affected; and to observe the gradual accession of the disease either in one or both eyes; or first in one and afterwards in another, with complete loss of vision, followed at last by changes of the structure of the eye.

53. When organic lesion of the pituitary and pineal glands has occasioned the disease, judging from the cases recorded by DE HAEN, WENZEL, VIEUSSENS, LEVYQUE, WARD, RULLIER, and RAYER, both eyes are generally gradually and equally affected, after the existence of cerebral symptoms, chiefly consisting of pain and weight referred to the more anterior parts of the head; of a repugnance to exertion, apathy, loss of memory, and weakness of the mental energies. In cases of sanguineous congestion, or hæmorrhages in the situations referred to, the attack is sudden, and the blindness is often not the most remarkable symptom.

54. In some cases resulting from organic disease within the head, cerebral symptoms, particularly those of an acute kind, are not complained of until the amaurosis is far advanced. In its progress, objects frequently seem to the patient disfigured or perverted. In many cases of amaurosis from organic change of the skull, membranes, or brain, the affection commences with intolerance of light, strabismus, giddiness, luminous spectra, convulsive motions of the eyes and eyelids, contracted pupil, and turgescence of the blood-vessels of the eyes, loss of hearing, smell or taste, or both, violent headach, rapidly followed by complete amaurosis, protrusion of the eyeball, and abolition of the external senses and of the powers of mind.

55. This species of amaurosis is often *complicated* with, or preceded by, epilepsy, paralysis, apoplexy, otorrhœa, or disease of the ears, hysteria, and various nervous affections. It is chiefly by attending to these antecedent disorders, or other slighter cerebral symptoms, that we can form any idea of the nature of the amaurosis. The appearance of the eye, and particularly of the pupil, is not to be depended upon; for, although the pupil is usually dilated and immoveable, the exceptions are too numerous to admit of considering it as an uniform occurrence.

56. *Spec. 7th, Amaurosis from disease of the optic nerves, or of their sheaths.* — This species of amaurosis always advances slowly, generally commencing in one eye, with a black cloud, which grows more and more dense, great disfigurement and perversion of objects, without pain of the head or eye. There is, however, a sensation of pressure at the bottom of the eye, as if forcing the eyeball from its socket. The pupil is generally,

from the commencement, much dilated, and angular, from irregular action of the iris. By degrees, according to BEER, glaucomatous change of the vitreous humour supervenes, and afterwards of the lens itself, but without any varicose affection of the vessels of the eye. At last the eyeball becomes somewhat smaller than natural, but complete atrophy does not ensue.

57. *Spec. 8th, Amaurosis from lesions of branches of the fifth nerve, &c.* — The experiments of BELL and MAGENDIE first threw light upon this cause or form of amaurosis. I believe that it is by no means infrequent. Four cases of it have come before me in private practice; in three of which the principal trunk or branches of the ophthalmic nerve were implicated. In one of these the amaurosis was very slight; in the other two it was very considerable, although not complete, and was a consecutive phenomenon of very extensive disease. I saw two of them, in consultation with respectable practitioners in my vicinity. The fourth case very recently occurred in a member of my own family. In it the frontal branch on the right side was pressed upon by a common boil; the sight of the eye was nearly altogether lost, but was soon restored when the boil broke.

58. Numerous cases are on record, in which partial amaurosis is said to have occurred after injuries and wounds of the eyebrows, cheeks, and forehead; or from the irritation and extraction of diseased teeth. The appearance of the disease from these causes was noticed by MORGAGNI, PINEL, BEER, WARDROP, TRAVERS, PENADA, RIBES, &c., before the functions of this nerve were so well known as they are now. Its occurrence from wounds of the eyebrows is mentioned even in the writings of HIPPOCRATES.

59. Amaurosis from these causes is, in some rare instances, *complicated* with facial neuralgia, toothach, rheumatism of the face, and tumours or abscesses developed in the vicinity of the eye, and within the cranium in the course of the fifth nerve. I met with it in a case of otorrhœa, terminating in caries of the bones, and extensive disease of the internal parts in the vicinity. It is also, in some cases, accompanied with paralysis of the upper lid, and in others with paralysis of different muscles of the eye. In these cases, the third or sixth nerves have, most probably, been chiefly affected. When the ophthalmic nerve is affected within the cranium, it is difficult, if not impossible, to determine the particular seat of lesion from the amaurotic symptoms. Facts have not been observed in sufficient number, and with requisite precision, to admit of any statement being made respecting the pupil and motions of the iris in this species of the disease. I believe, however, that serious organic, as well as functional, lesions of the organ may supervene to it.

60. There are other varieties of amaurosis particularised by BEER, WELLER, SANSON, and other German and French writers, some of them of rare or doubtful existence, or at least referable to the species into which I have here divided the disease. From amongst these I may enumerate the following: — Gouty amaurosis; rheumatic amaurosis; amaurosis from the sudden repulsion, or cure of cutaneous eruptions, or old ulcers; amaurosis from suppressed secretions and evacuations; puerperal amaurosis, &c. It is

evident that these are only occasional, and by no means frequent causes of the disease, which ought to be kept in recollection by the practitioner, but which can act only by inducing some one or other of the forms into which it has been divided; more particularly the *second, third, fourth, and sixth*. In as far as they may require a modified plan of treatment, they will receive attention in the sequel.

61. In addition to these, I may notice, the *cat's-eye amaurosis* of BEER, which is only met with in the old, debilitated, thin, and emaciated; particularly those who are grey or white-headed. At the commencement of this amaurosis, the iris retains its mobility; but it afterwards is slow and the pupil dilated. Deep in the bottom of the eye, a concave pale grey, or yellowish green, or reddish, variegated opacity is observed. The further the disease advances, the paler the bottom of the eye becomes, the paleness extending to the iris, until at last a slender vascular plexus—the ordinary ramification of the central artery and vein—may be discerned. With this state of the eye, decline or total abolition of vision is the consequence. This rare form of amaurosis seems to consist of a deficiency of the pigmentum nigrum, and of the tapetum of the uvea. It appears closely allied to far advanced glaucoma. This form of the disease is seldom or ever benefited by medical treatment.

62. V. DIAGNOSIS.—Amaurosis is liable to be mistaken for incipient *cataract*, and for *glaucoma*. When *cataract* is fully developed, the two diseases can scarcely be confounded. That a clear diagnosis should be made between incipient *cataract* and amaurosis is of the greatest importance in practice.—A. As to the impaired vision in both diseases at their commencement, it may be remarked that in *cataract*, the difficulty of sight increases very slowly, and is compared to a diffused mist, thin cloud, or gauze intervening between the eye and the object; whereas in *amaurosis*, the dimness or loss of sight is either sudden or partial, resembling a fly, spots, or motes covering parts of an object. However, a mist, or thin cloud, often is complained of in incipient amaurosis, and, increasing in density, at last deprives the patient of sight; but a complete deprivation of sight never occurs in *cataract*. As incipient *cataract* depends upon commencing opacity, generally at the centre of the lens, the appearance of a mist, &c., is generally most perceived when the patient looks straight forward; vision being more distinct when he looks sideways. This commonly does not obtain in amaurosis, although it sometimes does.

63. B. The degree of light which the patient desires is also important. When amaurosis depends upon insensibility of the retina, there is a great desire of strong light, and he sees the best at noonday, or when objects are brilliantly illuminated. The opposite of this obtains in *cataract*; for a strong light, causing the pupil to contract, the rays of light reflected from the object must pass chiefly through the central and more opaque part of the lens. In addition to this we should attend to the antecedent and attendant symptoms of amaurosis; especially vertigo, headach, disorder of the digestive organs, without which *cataract* usually commences.

64. C. Upon examining the pupil, incipient amaurosis presents either the jet-black colour of

health—excepting in the *cat's-eye amaurosis* of BEER, which is of rare occurrence, and presented to us under circumstances not to be mistaken,—or a paleness or greenness, visible only when the eye is examined in particular directions, constituting amaurosis with *glaucoma*. This appearance evidently arises from deficiency of the pigmentum nigrum, and incipient dissolution of the hyaloid membrane; and when it amounts to a high degree, constitutes the *cat's-eye amaurosis* of BEER.

65. Mr. MACKENZIE remarks on this subject, that attention to the following circumstances will generally enable the observer to distinguish glaucomatous amaurosis and *cataract*:—1st, The opacity in glaucoma is always greenish, whereas in incipient *cataract* it is always greyish. 2d, The opacity in glaucoma appears seated at a considerable distance behind the pupil, or deep in the vitreous humour; whereas in lenticular *cataract*, the opacity is close behind the pupil. In posterior capsular *cataract*, the opacity is deep in the eye, but is always streaked; whereas the glaucomatous reflection is always uniform, never spotted, nor radiated. 3d, Upon close examination of the surface of lenticular opacity by means of a double convex lens, it is seen slightly rough, somewhat dull, never smooth or polished—forming in these respects, a striking contrast to the appearances presented by glaucomatous opacity. 4th, The eyeball, in glaucomatous amaurosis, always feels firmer than natural; while in *cataract* it presents the usual degree of firmness. 5th, Glaucoma proceeds very slowly in its course, scarcely increasing for years; whereas the vision, in *cataract*, much more rapidly declines, and keeps pace with the growing opacity.

66. D. The mobility of the iris is a principal source of diagnosis. For, in incipient *cataract*, the contractions of the pupil are as extensive and as vivid as in health; but in incipient amaurosis the pupil is either dilated and fixed, or its motions limited and slow. Also, in the latter disease, the movements of the eyeballs and eyelids are often imperfect, or difficult; whereas no impediment of this description exists in *cataract*. In many cases of amaurosis, we observe a want of direction in the eyes, or a slight degree of strabismus, not infrequently with a want of power over the motions of the upper lid,—symptoms that never occur in *cataract*.

67. VI. PROGNOSIS.—This is unfavourable. When the cause of the disease is evident, and it is merely functional, or simply congestive or inflammatory, and the patient young, or in the prime of life, but under middle age, a complete cure is not infrequent. This may be obtained although much more rarely, even when the loss of sight is total. But in every case the predisposing and exciting causes, and the effects of remedies, must be taken into account in forming our prognosis. Much more commonly only partial amendment is produced. Amaurosis is generally less unfavourable when suddenly, than when slowly induced. When the pupil is only slightly dilated, still moveable, of its natural form, the eyeball neither firmer nor softer than in health, and no glaucoma present, the prognosis is obviously more favourable than when the pupil is fixed in the states either of expansion or contraction, or when the eyeball is either boggy or preternaturally hard, or when the bottom of the eye presents a greenish opacity.

68. If the attack has been sudden, and nearly complete, or if objects are seen in a perverted or distorted form, or double; if the amaurosis be attended with want of power in the muscles of the eyeball or eyelids, we should suspect that the cause consists of general or partial pressure, or other organic disease, within the cranium, which, although indicating both danger and the permanent loss of sight, will sometimes be removed by energetic treatment. If one amaurotic and paralytic symptom slowly supervene on another, we should dread the gradual development of tumours, cysts, exostosis, &c. within the head, the situation and nature of which can be suspected only, and chiefly from the nature of the attendant or preceding symptoms. But in all these the prognosis is necessarily very unfavourable.

69. VII. TREATMENT. — In order to employ remedies in this affection with any degree of benefit, it will be necessary to direct them with a very particular reference to the pathological conditions of the eyes, the brain, and system generally, as now pointed out. Having separated the disease into the foregoing species or varieties, in order that the treatment may be pointed out with greater precision, I proceed to detail the measures which I consider appropriate to each, conformably to the most experienced authors and to my own observation.

70. *A. Of the first species.* — The treatment of this, the most strictly functional form of the disease, should have strict reference to the causes which induced it, — whether those acting directly on the organ, or those which act indirectly, and in consequence of inducing disorder of other parts. When amaurosis proceeds from direct causes, either of a depressing or an exhausting nature, the appearance of the eye, as well as the character of the symptoms, require an attentive examination, chiefly with a view to ascertain the existence of inflammatory action, or even active congestion of the internal parts. A complete removal of the causes must be insisted on; and, if no symptoms indicative of inflammation (§ 46.) exist, but, on the contrary, debility, a languid circulation, *musæ volitantes*, or dark spectra, &c. (§ 39.), tonics and stimulants, both internally and externally, are required. A light, nutritious, and invigorating diet, with change of air, repose of the organs, moderate exercise, vegetable, and afterwards mineral tonics, and the usual means of improving the digestive organs, and promoting the functions of the bowels and secreting viscera, are in these cases chiefly to be depended on. Small doses of *strychnine*, or of the extract of *nux vomica*, may also be given (FORM. 541. 565.). When, however, we find evidence of congestion or increased vascular action of the internal parts of the eye to have been induced, the means to be employed in the next species must be resorted to.

71. When this species of amaurosis proceeds from interruption or disorder of the digestive functions, as indicated by the symptoms of such disorder, by a foul tongue, acidity and flatulence of stomach, and torpid bowels (§ 39.), *emetics*, as recommended by RICHTER, OTTO, SCHMUCKER, FLEMING, SCARPA, and MACKENZIE, may be exhibited; but, unless the symptoms of interrupted digestion, or of indigestible and injurious substances remaining upon the stomach, or of biliary obstruction, be unequivocally present, little ad-

vantage will be derived from them: in plethoric persons, or where these causes of disorder do not exist, they may be even injurious. Amaurosis from disorder of the digestive organ is generally imperfect, and sometimes slight; and its progress slow. In this form, SCARPA recommends *full vomiting* to be produced by the patient taking a spoonful, every half hour, of a solution of three grains of tartar emetic in four ounces of water; and, on the following day, opening powders to be commenced with, consisting of an ounce of bitartrate of potash and one grain of potassio-tartrate of antimony, divided into six equal parts. The patient is to take one of these parts in the morning, another four hours afterwards, and a third in the evening, for eight or ten successive days. The effects of these are, nausea, and increased evacuations from the bowels; and, in the course of a few days, vomiting. If, during their use the patient should complain of a bitter taste in the mouth, vain efforts at vomiting, and no improvement of sight, the emetic, as at first directed, is to be again taken; and this is to be repeated a third or fourth time, if the bitter taste, acid eructations, nausea, &c., continue. The repetition will often at last succeed in procuring the discharge of a yellowish or greenish matter from the stomach, to the relief of the head and eyes.

72. The stomach, and through it the liver, having been thus acted upon, the following resolvent pills of SCHMUCKER are to be taken, to the extent of fifteen grains, night and morning.

No. 11. R Gum. Sagapen., Gum. Galbani, Sapon. Venet., aa ʒj.; Rhei ʒjss.; Antimonii Pot.-Tartratis gr. xv.; Ext. Glycyrrh. ʒj. Divide in Pilul. gr. iij.

These pills are to be continued for four or six weeks. Instead of these, the pills recommended by RICHTER may be prescribed.

No. 12. R Gum. Ammoniaci, Gum. Assafoetid., Sap. Venet., Rad. Valerian., Summit. Arnicæ, aa ʒij.; Antimonii Potassio-Tartratis gr. xvij.; Syrup. q. s. M. et divide in Pilulas gr. iij.

From twenty to thirty grains are to be taken three times a day for some weeks.

73. If these succeed in improving the state of the stomach and sight, SCARPA directs means calculated to strengthen the digestive organs, and nervous system; such as the daily exhibition of bark and valerian, more particularly in periodic amaurosis; a light, digestible animal diet, with a moderate quantity of wine, and wholesome air and exercise. He further prescribes, as advised by THILENIUS and MURIGGIA, the *vapour of liquor ammoniac* directed to the eye, with the view of exciting the nerves of the organ; and employed, three or four times a day, so as to occasion each time a copious secretion of tears. In conjunction with the use of this vapour, other external stimulants, as blisters to the nape of the neck, behind the ears, or to the temples; irritation of the nerves of the nostrils by sternutative powders; and, lastly, sparks of electricity may be resorted to. Various volatile substances, spirituous, saline, and oleaginous, have been recommended to be applied to the eyes, either in a state of vapour, or of solution, and dropped into them, by WARNER, SAGAR, MANARDUS, DUNCKLER, CHOMEL, ST. YVES, and SCHMUCKER; but these require to be cautiously resorted to. Substances of a like description have also been prescribed in the form of *collyria*, in this species of amaurosis. PLENCK recommends for this purpose a drachm of the *crocus metal-*

lorum dissolved in rose-water; or a portion of the following:—

No. 13. R. Spirit. Lillior. Conval. Spir. Lavand., Spir. Rorismar., Hydrochlor. Ammon., aâ ʒj.; Spir. Bals. Vitæ Hoffmann. ʒss. M.

to be poured in the palm of the hand, and held before the eyes. The application of cold and slightly stimulating washes and baths to the eye, and bathing the whole head, or eyes, in cold water, have been approved by RICHTER and BEER. Mr. TRAVERS, however, states, that he has never obtained any decided advantage, in amaurosis, from applications made directly to the eyes. Both electricity and galvanism have received the recommendation of WARE, LENTIN (*Beurträge*, iv. b. p. 102.), and OSSIANDER (*Abhandl. Med. Soc. zu Erlang.* i. b. No. 8.). *Moxas* applied in the course of the facial nerves have been used by LARREY; and the *actual cautery* behind the ears by KILLOBOVITCH. (*Archives Génér. de Méd.* t. xvi. p. 452.)

74. In this species of amaurosis, both in cases of the above description as well in those which proceed from the over exertion of the sight, the external application of strychnine promises to be of considerable advantage. Mr. LISTON, Dr. SNORT (*Lond. Med. Gaz.* vol. v. p. 541.), and Dr. HEATHCOTE (*Medico-Chirurgical Rev.*, July 1830), have thus employed it with decided benefit. After blistering the temples, and removing the cuticle, from one eighth to one fourth of a grain of pure strychnine was applied to the denuded surface on each side daily, and the application renewed each day, and gradually increased to a grain. In one case the quantity was increased to three grains, but it is seldom requisite, and it may sometimes not be safe, to exceed half this quantity. In some cases it will be necessary to re-blister, oftener than once, the surface, after repeated applications of the strychnine. Cataplasms of *capsicum* have also been employed with advantage to the temples. GAIN mentions them with approbation; and I have seen them used in amaurosis, with decided benefit, by the native doctors in warm climates. HOFFMANN and TREV employed the cajepout oil in this manner, and WARNER the animal oil of Dippel.

75. Mr. TRAVERS and Mr. LAWRENCE are not advocates for the use of emetics. The former prefers to remove the gastric disorder by a course of blue pill, with gentle saline aperients and vegetable tonics. He recommends the combination of blue pill with colocynth, rhubarb, and aloes; and of soda with calumba, gentian, or rhubarb; with the view of promoting or regulating the abdominal functions. After these he advises the use of general tonics, as the mineral acids, bark, steel, and arsenic. Mr. LAWRENCE chiefly approves of attention to the general health, by residence in a pure air; out-of-door exercise; mild, plain, but nutritious food; gentle aperients, and occasionally an active purgative; repose of the affected organ; counter-irritation by a succession of blisters, an open blister, or setons. BEER is also against the use of emetics. He prefers the employment of brisk cathartics; followed by the use of anthelmintics, when we suspect the presence of worms in the bowels. Rubefacients, stimulants, and blisters to the temples and eyebrows, are favourably mentioned by him.

76. There can be no doubt of the propriety of the measures recommended by the above writers;

but are we to remain content with them alone, in cases where amendment from them is either slow or not apparent? I think not; and therefore are we required to devise additional means. Those already recommended by the eminent continental authorities, as stated above (§ 71, 72.), and the external medication already described (§ 73, 74.), have both authority and reason in their favour, if duly followed. But it may be useful to suggest others. For, in cases of this disease, the practitioner will have reason oftener to regret the want, than to be perplexed by a diversity, of rational resources.

77. After having had recourse to evacuations, to emetics with great caution, and, under the circumstances stated above (§ 71.), always to aperients, alteratives, and occasionally to brisk purgatives, promoted by enemata, suited to the peculiarities of the case, and repeated as long as the secretions are impeded, and the evacuations offensive, or of an unhealthy colour, other internal means must be sought for, if necessary. Amongst these, in this species of the disease, camphor combined with *arnica*, and in considerable doses, has been recommended by FLEMMING (*Hufeland's Journ.* &c. Jan. 1810, and May 1812); the *rhus toxicodendron*, or the *rhus radicans*, in the form of tincture, by BASSE and HUFELAND (*Journ. der Pract. Heilk.* &c. Jan. 1811); and phosphorus by LOEBEL (*Horn's Archiv.* Nov. 1812, p. 397.) Musk, castor, assafoetida, valerian, and zinc, have also been favourably noticed by BEER.

78. It is chiefly in this form of the disease that advantage, if any, will be derived from the use of *aconitum*, which, however, has received the approbation of BOEHMER, COLLIN, STOLLER, REINHOLD, GESNER, and other respectable authorities, particularly when the affection is connected with chronic rheumatism, or atonic gout, or occurs in the gouty and rheumatic diathesis. *Guaiacum* has been recommended by WINTRINGHAM; and, under the circumstances of disease now alluded to, particularly when combined with camphor and ammonia, and given after due alvine evacuations have been procured, is calculated to prove beneficial. The *arnica montana*, which has been prescribed by BALDINGER, COLLIN, FRANCK, THULENIUS, and ANGELI, is applicable to this form of amaurosis only. It is most probably from having employed it in very different states of the disease,—in the inflammatory, or those depending upon organic change within the head,—that it has been disapproved of by RICHTER and SCHMUCKER.

79. The chief complications of functional amaurosis require no very different treatment to that which has been described. The not infrequent association of the disease with worms demands the use of anthelmintics, followed by purgatives, and the administration of vermifuge enemata, &c. (see Art. Worms), and afterwards by vegetable or mineral tonics. But, in the majority of cases of even functional amaurosis, the use of the preparations of iron requires caution. When the disease is occasioned by lead, or accompanied with the lead colic, or attended by paralysis of any other parts of the body, the exhibition of calomel, with camphor and small doses of opium, followed by purgatives and antispasmodic and aperient enemata, is extremely serviceable. After the secretions and functions of the abdominal viscera are restored by these means, strychnine, or the

extract of *nux vomica*, may be prescribed both internally and topically. (FORM. 542. 565.) The connection of the disease with hysteria, hypochondriasis, obstructions of any of the abdominal secretions, chiefly requires the combination of antispasmodics with aperients; chlorine, iodine, or sulphureous baths; the occasional exhibition of a brisk purgative; and, afterwards, the warm salt-water bath, tonics with stimulants, and strict attention to the secretions and functions of the digestive organs, and to diet, air, and exercise. After all obstruction is removed, cold bathing, or chalybeate or salt-water baths, followed by frictions of the cutaneous surface, may be used.

80. *B. Of the second species.*—When amaurosis is attended with those symptoms which I have described as marking active congestion of the internal parts of the eye, or of the head or thoracic viscera (§ 41.), a very different treatment to that enjoined above is requisite. In the first species of amaurosis, *blood-letting* is generally prejudicial—it has even caused the disease; but, in the congestive species, blood-letting, either general or local, or both, according to the circumstances of the case, is indispensable. In every form of the disease the means of cure must be regulated by the apparent vascularity of the eye, the plethoric state of the countenance and body, and by the state of the arterial pulse, examined, not only at the wrists, but also in the carotids and temples.

After depletion, to an extent which the well-informed practitioner will be led to adopt according to the particular characters of the case, the promotion of the alvine discharges, and of the cutaneous and alvine secretions, will next require his attention, as salutary modes of derivation and evacuation; and afterwards the application of blisters, setons, issues, and other counter-irritants, behind the ears, or to the nape of the neck, will generally be necessary to complete, or to render permanent, the cure. The ointment of the potassium-tartrate of antimony, moxas, the mezereon issue, the actual cautery to the nape of the neck, or to the occiput, and erethines, have severally been recommended by eminent continental writers in this state of the disease.

81. The *shower-bath*, sponging the head with cold water night and morning, the *cold douche*, or the effusion of a stream of cold water on the head, are means which ought not to be neglected in those cases in which the congestion is of an active character, or approaches to the inflammatory state. When this form of the disease is consecutive of interrupted or suppressed discharges or evacuations, the restoration of these must be attempted. If the menses be suppressed, leeches to the pudenda, or the insides of the tops of the thighs; or bleeding from the feet; the preparations of iodine, aloetic purgatives, and other emmenagogues; stimulating pediluvia, and the *hip-bath*, with the other means usually resorted to in cases of amenorrhœa, are to be employed. If it proceed from suppressed hæmorrhoids, leeches may be applied to the vicinity of the anus, and purgatives, with calomel, colocynth, and aloes, prescribed. If it supervene on the disappearance of gout or rheumatism, sinapisms and irritating cataplasms may be directed to the extremities, and free alvine evacuations procured; after which colicium, combined with alkalis or magnesia,

and, in some cases, with ammonia or camphor, may be exhibited, or aconitum combined with antimonials, and purified sulphur; and rubefacients applied behind the ears, or to the temples. When it appears after the suppression of eruptions, and healing of old ulcers, the use of the tartar emetic ointment, setons, and perpetual blisters behind the ears, are particularly indicated. If it follows a suppressed cold, WELLES recommends weak sternutatories, with calomel or hellebore.

82. Mr. TRAVERS has very justly remarked, that a loss of balance of the circulation, producing undue determination of blood to the head, often exists independently of general plethora, and is aggravated by sanguineous depletion. It is sometimes even met with in corpulent persons; and is not infrequent after over-excitement and chronic inflammation. Instead of requiring loss of blood for its removal, this state of the disease demands an equalisation of the circulation, by promoting the various secretions, and the derivation of the excessive supply to other parts by the means now stated, assisted by an abstemious and regular diet, gentle exercise in the open air, the promotion of the functions of the liver and bowels, and the means usually employed to benefit the general health. Even in some of these cases, the local means noticed above, as the vapours of ammonia, &c. (§ 73.), may be serviceable in restoring the tone of the vessels of the eyes.

83. *C. Of the third species.*—Inflammation of the internal parts of the eye, particularly of the retina, requires decision, in the more intense cases, and a vigorous but judicious application of the usual antiphlogistic remedies. In the slighter cases, the exact nature of the disease may be mistaken for either of the foregoing species. Slight or slow inflammatory action may exist without any material affection of the pulse, or pain of the organ; but the appearance of the blood-vessels of the sclerotic, and the state of the iris, will often indicate its presence when other signs are wanting. When the attack is acute, both general and local depletions are required. In these cases PLENCK has advised the performance of arteriotomy; SPIGELIUS and HOFFMANN of blood-letting from the frontal vein; and SAUVAGES from the jugulars. But vascular depletion is not to be relied upon alone. Active evacuations from the bowels, determination to the skin by small and repeated doses of antimonials, and the use of the tartar emetic blister or plaster behind the ears, or to the nape of the neck, are to be also adopted.

84. If these means fail of producing a very decided improvement in a very short time, we must endeavour to affect the mouth slightly with mercury, without producing salivation. In order that this may be done with rapidity, and with as little mercury as possible, the preparations of this mineral to be employed will be advantageously combined with James's powder, or compound powder of antimony, and small doses of camphor. The treatment is, in such cases, similar to that usually resorted to in iritis. Much of the advantages to be procured from the use of mercury in this form of amaurosis, as well as in iritis, depends upon the promptitude with which it is employed. In this TRAVERS, LAWRENCE, MACKENZIE, and others agree. Indeed, the use of calomel, and other preparations of mercury, either alone, or com-

bined with other substances, has been adopted in the inflammatory states of amaurosis, from the time of HEISTER and BOERHAAVE, BANG, HUD-EMANN, SCHMUCKER, ZUCKER, and BREITING, agree in recommending them. BOETTCHER advises the combination of calomel with belladonna; and HEY, calomel with camphor; both being judicious modes of combining this medicine. MEAD, STAHL, HOFFMANN, and ISENFLAMM, advise the production of salivation; but I agree with TRAVERS in considering the affection of the mouth as sufficient. The use of mercury is much praised by BEER in such cases, as well as in those of a syphilitic origin, or which are complicated with engorgement of any of the abdominal viscera. Care should be had not to employ mercury in debilitated or scorbutic persons, and when the eye is soft or boggy. Many of the continental writers, and Mr. WARE, prefer the bichloride to other preparations. It is best exhibited, as recommended by VAN SWIETEN, dissolved in brandy, and taken in a basin of sago or gruel. It may be continued for six weeks, or even longer.

85. The success which has resulted from the exhibition of the *oleum terebinthinæ* in iritis induced me to prescribe it, after depletions, in two cases of this form of amaurosis, and with satisfactory results in both. In persons far advanced in life, in scrofulous subjects, and in debilitated persons, this oil is certainly a less hazardous medicine than the mercury exhibited so as to affect the system.

86. In the slighter or more chronic inflammatory forms of amaurosis, particularly when met with in the description of subjects just now alluded to, much circumspection is necessary in the use of depletions; general blood-letting is here inadmissible, particularly when this class of patients are ill-fed, and live in close and ill ventilated streets and apartments in large towns, and local depletions only are indicated. In cases of this description, and under these circumstances, the *oleum terebinthinæ* will prove a valuable medicine; and even, although we may deplete thus locally, the internal exhibition of tonics, with a nutritious diet, attention to the alvine secretions and evacuations, and a wholesome air, will prove the most beneficial remedies.

87. This form of amaurosis, as well as the preceding, will occasionally supervene from suppressed evacuations and eruptions, and, more rarely, from misplaced gout and rheumatism. (§ 48.) In such cases, the treatment already recommended, as appropriate to each of these (§ 81.) will be equally applicable here.

88. Besides the above means, it has been recommended by BROMFIELD, to insert an issue in the scalp; by HOFFMANN, to apply leeches to the insides of the nostrils; by numerous authors, to employ errhines and sternutatives, with the view of provoking a copious secretion from the Schneiderian membrane; and by as many others, to use the actual or potential cautery, setons, moxas, &c. to the nape of the neck, or to the occiput. Leeches and counter-irritants are safe, and sometimes useful, remedies in this and the preceding species; but errhines and sternutatives may be hurtful, unless the affection has arisen from suppressed discharges from the nostrils. They are most serviceable in the functional state of the disease. The safest that can be employed in this

species of amaurosis is the one recommended by the late Mr. WARE. It consists of ten grains of the hydrargyrus sulphuratus, well mixed with a drachm of common sugar: a small pinch of it generally produces a copious discharge of mucus from the nose.

89. *D. Of the fourth, and remaining species.*—When we have reason to suspect that the amaurosis depends upon advanced organic lesion of the internal parts of the organ, consequent upon inflammation, we should still bear in mind that, with the supervention of such lesion, whatever it may be, the inflammatory action seldom altogether subsides, but continues, more or less, in a chronic, atonic, or disorganising form. Therefore the propriety of still having recourse to local depletions, particularly if these have been neglected early in the disease, to purgatives, derivatives, or revulsants; the cold douche to the head; and, afterwards, to the use of stimulating vapours, when we have reason to suspect that the change continues rather in consequence of lost tone of the vessels, and inaction of the absorbents, than from increased action. Under such circumstances, the vapour of camphor and acetic acid, or of the liquor ammoniæ, may be tried.

90. *a.* If the amaurosis have arisen from *external injury of the ball of the eye*, or concussion of the organ (§ 51.), the chief indication is to prevent, or to repress, increased vascular action, by the means already recommended; to attend to diet and regimen, and to keep the organ in a quiet inactive state for some time; after which, if the affection still continue, the treatment must be directed according to the particular lesion, functional or organic, that may have been primarily or consecutively produced.

91. *b.* When the history of the case leads us to suspect the dependence of this affection upon *disease within the head* (§ 52.), or tumours pressing upon the *optic nerve*, &c. (§ 56.), the treatment must necessarily be directed, according as the symptoms referable chiefly to the head may lead us to infer the nature of the primary lesion. If such symptoms, particularly the temperature of the head, and the action of the carotids, indicate the existence of congestion, interrupted circulation, or increased action, the treatment must be accordingly. But, under almost every circumstance, counter-irritation, and external as well as internal revulsants, will prove safe, and sometimes serviceable, means of cure.

92. If we have reason to suspect the formation of tumours; thickening, or other change, of the membranes or of the bones, particularly as a consequence of syphilis; and extravasations of blood, or of serum, within the cranium, or in the course of the optic nerves, &c. (§ 52.), the internal use of the preparations of *iodine*, and particularly of the *iodide of mercury* or of *potassium* (see FORM, 323, 324.), should not be overlooked. I have employed these preparations with much benefit in three cases of amaurosis connected with paralysis; two of them consequent upon apoplectic seizures. In the intervals between the courses of iodine, deobstruents, and alterative doses of blue pill, with the extracts of sarsaparilla and taraxacum, or with the decoction or other preparations of sarsaparilla, should be prescribed.

93. c. When the affection seems connected with *lesion of the other nerves subservient to vision* (§ 57.), the treatment must necessarily depend upon the seat and nature of this lesion, and, in some rarer cases, upon the state of the associated derangement. If it be connected with neuralgia of the nerves of the face, disorder or irritation of these nerves may exist at their origin, or in their course through the membranes and bones of the cranium. The cause may also be external—in a diseased tooth or stump, or a partially separated external branch of the ophthalmic trunk of the fifth nerve. In all such cases, as well as in the other forms, states, and associations, of the fifth, sixth, seventh, and eighth species, which have been enumerated, the treatment must vary in each, and be directed according to the very numerous pathological conditions, which the well-informed pathologist will detect, either as their efficient causes, or as their related effects.

94. Throughout the treatment of this disease, the practitioner should keep the following facts in recollection:—1st, an appropriate, and hence successful, method of cure should have an intimate relation to both the remote and proximate causes of the disease, and the natural or morbid diathesis of the patient: 2d, It must be directed after a minute inspection of the eyes, and examination into symptoms connected with the head and the digestive viscera: 3d, It must be modified according to the nature of its related, associated, and symptomatic disorders: and, 4th, That much of the success will often depend upon the strict regulation of the patient's digestive and organic functions; upon diet and regimen; and upon a regulated exercise both of the organ of sight and of the body, with a pure and temperate air. Keeping these indications in recollection, the practitioner will modify and adapt the treatment to the presumed nature, seat, complication, and relations of the disease.

CLASSIF. 2. Class, Diseases of the Respiratory Function; 2. Order, Affecting the Lungs, their Membranes, or Motive Power (Good). II. CLASS, I. ORDER (Author, see Preface).

I. DEFIN. *Acute constrictory pain at the lower part of the sternum, inclining to the left side, and extending to the arm, accompanied with great anxiety, difficulty of breathing, tendency to syncope, and feeling of approaching dissolution.*

2. This affection was not recognised as a distinct disease by medical authors, until Dr. HEBERDEN described it as such in the Medical Transactions of the London College of Physicians (vols. ii. and iii.); but the works of MORGAGNI and HOFFMANN show that they were not unacquainted with it in practice. It was also noticed by POTER (*Opera*, No. 22. p. 302.), under the head "Respirandi difficultas quæ per intervalla deambulantibus incidit;" and he remarks respecting it, that the attacks were sometimes so severe that persons had been suddenly carried off by them. Obscure notices of affections, which probably were of this nature in some instances, may also be detected in authors from HIPPOCRATES downwards. From amongst these, the reader may refer to ARETEUS (*Opera*, p. 7. Oxon. 1723), CÆLIUS AURELIANUS (lib. ii. c. i. p. 348.), BARTELETTI, (*Methodus in Dyspnoæa*, Bon. 1632), and others, adduced by ZECHINELLI (*Sulla Angina di Petto*, Pad. 1813), who supposes that the case of SENECA (*Opera*, t. ii. p. 136.), which he has himself described by the term *suppirium*, was actually this malady. Dr. CULLEN has passed Angina Pectoris over in his work; but it has been well described by Drs. FOTHERGILL, WALL, DUNCAN, BUTLER, PERCIVAL, DARWIN, MACBRIDE, HAMILTON, MACQUEEN, JOHNSTONE, HAYGARTH, PARRY, NICHOLL, and GOOD, in this country; and by JURINE, BRERA, LENTIN, DESPORTES, KREYSIG, RITTER, ZECHINELLI, and STOELLER, on the Continent, and by Dr. CHAPMAN, in America.

3. PATHOLOGY.—I. SYMPTOMS.—An attack of this disease is often preceded by considerable derangement of the digestive organs, especially by flatulence, acid or acrid eructations, or other symptoms of indigestion, with torpid bowels, pains in the limbs, and occasional spasms about the chest; but it frequently also attacks a patient, particularly when walking or ascending an eminence, without any, or with but slight premonition.

4. *A.* In its *acute form* the patient is seized with a sense of painful constriction of the chest, particularly at the cardiac region, about the lower part of the sternum, inclining to the left and extending to the left, occasionally also to the right, arm—at first no further than the insertion of the deltoid muscle; but the pain often successively reaches to the elbows, wrists, and sometimes even to the fingers. This is the mildest form of the disease, and soon subsides with the disappearance of its exciting cause.

5. In the more violent form of the attack, the pain and sense of constriction in the chest, and pain in the left arm, which also frequently extends to the right, amount to excruciating agony; being likened, by LAENNEC, to the piercing of nails or the laceration by the claws of animals. This feeling is accompanied by a sense of syncope or suffocation, sometimes with suffocative orthopnoea, convulsive dyspnoea, and palpitations; always with extreme anxiety, and a sense of approaching dissolution. The suffocative sensation is characterised by concomitant tightness and fulness of the chest, and flatulent distension of the stomach, and irritative feeling in this organ, which is relieved by eructations. During this period the pulse is variously affected, sometimes little changed, at other times extremely weak, irregular, indistinct, or intermittent; and occasionally it is full, active, and bounding. If the attack has been induced by walking or exercise, the patient suddenly stands still, from a feeling that perseverance in either would produce a total suspension of living power. In the slighter attacks, or early in the disease, rest merely will often immediately remove it; but this is seldom the case in the protracted and severe forms in which it frequently occurs.

6. The paroxysm continues from a few minutes to one or more hours, according to the severity and the duration of the disease. When the malady has assumed a chronic form, and its attacks occur during the night, or when the patient is at rest, the paroxysm is less violent, but generally of much longer duration; whereas, when it is induced by exertion, &c., it is of extreme violence, but of short continuance; the average duration of the fit may be about half an hour. Upon its cessation the patient merely retains a slight feeling of the various symptoms, with numbness of the arms, particularly the left. When the disease is of short standing, the paroxysms occur at long intervals, which are gradually shortened, until there is but little exemption from them, and the affection assumes a less acute character.

7. *B.* The *chronic form* of the disease is characterised by the circumstance of its being frequently a consequence of the acute; by the occurrence of the fit from the slightest causes, and after short or imperfect intervals of exemption; by its recurrence when the patient is at rest or asleep; and by its much longer duration, but less extreme violence. Even if this form be induced by exercise, rest has little influence in shortening its duration, as in the preceding; and the paroxysm has been protracted, not only for some hours, but even for several days. Palpitation of the heart, irregular and intermitting pulse, are more frequently concomitants of this state of the disease than of the other. In the case of a very eminent and learned member of the profession, whom I

long attended in this form of the disease, the attack has often continued as now described, with little remission, for several weeks. Sometimes the irregularity of the pulse is observed only during the paroxysm; but in some cases it is continued, as Dr. FOTHERGILL has correctly remarked, during the intervals, particularly when they are marked by imperfect relief.

8. This form of the disease may also occur primarily. It has twice presented itself to me in this manner. During the severity of the attack, leipthymia, a feeling of dissolution from the intense agony, and these followed by palpitations, and an irregular state of the pulse, generally occur. In some cases the agonizing pain extends, not only to the arm or arms, but ascends also up the throat and lower jaw, accompanied with a severe sensation of spastic constriction. In the majority of cases the above sensations are only present when excited by motion, by assuming suddenly the erect posture, or even by attempting to read; a neuralgic kind of pain generally, however, being felt under the sternum, and extending to the arms: but in some cases, and in two which occurred to me, the exacerbations were often referable to no very evident cause, they sometimes occurring during the night, although the above causes generally induced them.

9. Notwithstanding the remarkable distress characterising the paroxysm, this disease, particularly in its acute state, sometimes does not early affect the constitution, or entail any permanent lesion; the patient often enjoying tolerable health in the intermissions, and performing all his functions naturally, and without embarrassment, until shortly before an attack. After its protracted continuance, however, the vital energies of the frame, particularly as they are manifested in the digestive and circulating organs, give way. Marked disorder of the chylopoietic viscera, attended with various dyspeptic symptoms, occasionally with great irritability of the stomach and bowels, impeded respiration, anxious and pale countenance, flabby state of the integuments and muscles, marked derangement of the circulation, œdema, dropsy, &c., at last supervene. But it more generally happens that the patient is carried suddenly off by a paroxysm before this state of the system is occasioned; or he sinks under the complicated derangement proceeding from an attack, and from some one of the organic changes which the continuance and repeated fits of the disease had induced.

10. II. CAUSES.—1. *Predisposing*.—This disease usually attacks the middle aged, and those beyond it; and men much more frequently than women. Of nearly one hundred cases, about seventy were upwards of fifty years of age; and seventy-nine out of the number were males; nearly one half terminated fatally, and almost the whole of them suddenly. It has been said also to occur more commonly in robust and corpulent persons with short necks. But JURINE and CHAPMAN dispute this. My own experience agrees with theirs in respect of its being equally common in persons of a spare as of a full habit. It is most prevalent in those of gouty and rheumatic diathesis, and who lead an indolent, or studious and sedentary life, or who have been subjected to much and continued anxiety and distress of mind, or indulged in much, food, and spirituous or other

liquors. JUNINE and PARR state that they have scarcely met with it under fifty years of age. The most violent and distinctly marked case of it which ever came before me occurred in a gentleman at the age of thirty-four. During 1821, I attended an unmarried lady, aged twenty-six, who laboured under it in a slighter form; and recently, in 1830, another single female, at the age of twenty-five, came under my care, with the disease in its most violent grade. In both these females it seemed perfectly unconnected with uterine disturbance, menstruation being regular, and no tendency to hysteria having at any time evinced itself, or could be detected, my attention having been directed to this point. They both ultimately recovered, after a long treatment, and the employment of very decided measures. Nearly all the cases which have come under my observation were more or less referable to mental causes, particularly to disappointment, anxiety, and other depressing passions. Dr. HAMILTON conceives that there is an hereditary disposition to the affection. If we consider it to be of gouty origin, as contended for by BUTTER, MACQUEEN, RITTER, STOELLER, THULENIUS, ELSNER, and CHAPMAN, an hereditary disposition may be also conceded. But, although very satisfactory proofs have been adduced by these authors, and particularly by Dr. CHAPMAN, in an able paper he has recently published on this disease (*American Journ. of Med. Sciences*, No. xiii. p. 67.), yet it does not seem always to depend upon gout. Of the four cases which occurred to Dr. BLACK, of Newry, one only was subject to gout (*Med. Chir. Trans.* vol. vii.).

11. 2d. The disease is usually excited by walking, especially walking against the wind, or up hill; by ascending a flight of stairs, or any acclivity, particularly when the stomach is full or distended by flatus. It is also readily induced by either the exciting or the depressing passions, and by whatever perturbs the mind or occasions emotion. It may also be induced by the most trifling causes, in some susceptible and irritable habits, as by gentle walking, coughing, speaking, or reading aloud; by suddenly assuming the erect posture; by straining at stool; or even by a meal, however moderate, &c. It may also occur in a state of absolute repose, particularly when the disease has become chronic; and the patient may be roused from sleep by an attack.

12. I have seen it occasioned by rapid changes of temperature, particularly by a rapid change to great cold; but different persons seem differently affected by extreme states of atmospheric temperature. In some slight cases the fit has been shortened, by the patient struggling to overcome it, by frequently attempting to make a full inspiration; but this has also failed. The patient is incapable of making this attempt in the more severe paroxysms.

13. III. DIAGNOSIS. — Angina pectoris is more liable to be confounded with asthma than with any other disease. But a close attention to the phenomena attending upon both affections, will readily disclose a very great difference between them. The paroxysms of asthma always come on during the night, or at the close of the day; they are characterised by a heavy dyspnoea, wheezing, and cough, are relieved by expectoration and exposure to fresh air, and subside gra-

dually towards morning. They are not excited in the same way, nor by similar causes, nor marked by the acute and peculiar pain in the sternum and left arm, which is distinctive of angina pectoris. The stethoscope and percussion furnish us with no signs peculiar to the disease under consideration, unless it be complicated, as is sometimes the case, with organic lesion of the heart and lungs, or with effusion of fluid within the cavity of the pleura or pericardium, when they materially assist us in ascertaining the nature of the complication; and they also serve, by enabling us to ascertain other affections of the heart, to distinguish between it and them.

14. IV. PROGNOSIS. — In recent cases, of no very violent character, recovery will frequently take place under judicious management. But when the disease has become inveterate from neglect, or from being associated with, or from having given rise to, organic lesion, and when it has appeared in a decayed constitution, or has been preceded by other diseases of the heart or lungs, an unfavourable result should be apprehended sooner or later to take place; but the period of its occurrence is uncertain; and the event is generally sudden — sometimes like an electric shock; the movements of the heart being instantly arrested. This issue is often occasioned by a full meal, or by exercise or mental emotions; but it also occurs in old or chronic cases, when the patient is at rest, and apparently uninfluenced by any circumstance or occurrence. When it is followed by symptoms of effusion of fluid within the thorax, or œdema of the extremities, a fatal termination is seldom far distant.

15. V. PROXIMATE CAUSE, &c. — Notwithstanding the number of examinations which have been made after death from this disease, but little light has been thrown upon it. This is not so much owing to the absence of morbid appearances as to the extreme diversity of those which have been observed. Like epilepsy or dyspnoea, it has presented almost every lesion to which the organs which it affects are liable. Many of these may be viewed as accidental concomitants, or as concurrent causes; and not infrequently as results of the repeated functional disturbance occurring during repeated attacks. In several instances, not the slightest morbid appearance could be detected; but more frequently the heart and the large vessels in its vicinity have presented marks of disease, generally varied in its nature, and opposite as to its characters. The most common of these are ossification of the coronary arteries; ossification of the valves of the heart or of the arterial trunks; enlargement of some of the cavities of the heart, either with diminished or increased thickness of their parietes, but most frequently with fatty degeneration, or softening, paleness, and tenuity of the muscular structure of the organ; varicose dilatation of the coronary veins (BRERA); depositions of adipose matter, to the extent of impeding its functions; effusions of serum, blood, &c. into the pericardium or cavity of the pleura, &c. (FOURNELLE, BLACK, &c.) It has justly been remarked, by Dr. UWINS, "that there is scarcely any malformation of the heart or its blood-vessels, that has not been occasionally found after death, from what would be considered angina pectoris: while, on the other hand, individuals have fallen victims to the affection, fully marked, and the most accu-

rate post mortem examination has not been able to detect the slightest indication of structural derangement."—(*Compend. of Theoret. and Pract. Med.*)—In some cases the only morbid appearances observed have been in other, and distant organs, from that which seems to be, if not the chief seat of the disease, at least the organ chiefly affected in its functions by it—the heart and large vessels having been altogether exempt from lesion. These appearances were adhesions of the serous surface of the lungs to adjoining parts; serous effusions into the pleura; thickening of the respiratory mucous surface; dilatation of the bronchi; œdema of the intervesicular cellular tissue of the lungs; abscess and tumours in the mediastinum; ossification of the cartilages of the ribs (WICHMANN, JAHN); tubercles, enlargement, scirrhosity, &c. of the liver (PERCIVAL, LATHAM, BRERA, and WALKER); scirrhosis of the pylorus, &c.

16. These lesions serve less to throw light on the precise nature of the disease than an attentive examination of the morbid phenomena during the life of the patient, and a calm appreciation of their relations, particularly with respect to the agents tending to diminish, remove, or to exasperate them. This affection has been considered by many authors as spasmodic, "although the part immediately concerned seems not to have been designated or understood." Dr. CHAPMAN remarks, that this hypothesis is rendered probable, by the general complexion of the disease—its causes, symptoms, and cure—and by its analogy to other disorders confessedly of this character.

17. Dr. FOTHERGILL supposed it to be occasioned by obesity, and particularly by a collection of fat about the heart; he also considered that it was sometimes symptomatic of water in the pericardium or cavity of the thorax. PARRY, JENNER, BURNS, KREYSIG, BOSTOCK, and some others, have viewed this affection as a species of syncope occasioned by the accumulation of blood in the heart, from an ossification of the coronary arteries. Drs. HOSACK and FORBES conceive that it most frequently arises from a plethoric state of the blood vessels, more especially from a disproportionate accumulation of blood in the heart and large vessels. To the first and second of these opinions it may be objected, that there is no obvious connection between the effect and the cause; for, as the cause is permanent, the effect should be continued, or at least present but little abatement, whereas the intermissions between the paroxysms are often characterised by a return of the healthy functions. It may be further stated, in opposition to this hypothesis, that many fatal cases have occurred in which this particular lesion was not found on dissection. LAENNEC states that he has examined several subjects who had laboured under this disease, and in none of them did he find the coronary arteries ossified. Besides, cases are recorded by MORGAGNI, SENAC, WATSON, CORVISART, ANDRAL, and others, in which ossification of these vessels were not productive, during life, of the sufferings characterising this disease. Indeed the coronary arteries were often found ossified in old persons, who had not complained during life of any affection of the heart, and who certainly never were attacked by this malady. As to the last of the above opinions, viz. that adopted by Dr.

HOSACK, Dr. CHAPMAN has very justly observed, "that even allowing the fulness and irregularity of the circulation contended for, which I am by no means disposed to do, as uniform concomitants, these I should take to be rather the effects of previous irritation or excitement, than the cause of the disease. Do we not also know, that such a condition of the vessels can exist without inducing angina pectoris? Were fulness and irregularity in the circulation only required for the production of the disease, instead of a rare, would we not have it as a daily occurrence? The fact, moreover, is, that angina pectoris, though oftener, perhaps, attacking the plethoric, is to be met with, as I have before said, in the feeble and attenuated." I may add to this, that the severest case of the disease which has ever occurred to me was that of a gentleman who had suffered severely from repeated and profuse hæmoptysis, and other symptoms of disease of the lungs. All these disappeared, but were followed, after some time, by angina pectoris. He was feeble and attenuated; but it was considered advisable to try the effect of blood-letting to a moderate extent: this gave no relief; it was repeated, but the symptoms were evidently aggravated by the measure.

18. Dr. JURINE considers the disease as a nervous affection; and he supports this opinion by referring to the sudden and unexpected manner of its attack—to its sudden termination in death, or restoration to health—the nature of the exciting causes of the paroxysm—the equality and regularity of the pulse, in the majority of cases, during the paroxysm—to the state of the respiration—to the painful sensation extending to the upper extremities—and lastly, to the circumstance of antispasmodics being beneficial in its treatment. The proximate cause, he adds, consists of an affection of the pulmonary nerves, disturbing the functions of the lungs, impairing the decarbonisation of the blood, and producing the pain in the sternum. This affection of the pulmonary nerves is communicated to the cardiac plexus, and deranges, secondarily, the heart and large vessels. The imperfect decarbonisation of the blood diminishes its stimulating influence on the heart and lungs, giving rise to repeated attacks, until it occasions the death of those organs, and then of the brain.

19. MM. DESPOTES and LAENNEC have adopted a nearly similar view of the disease, with this difference, that they consider its particular seat may vary according to circumstances. Thus, M. LAENNEC states, that when there exists, simultaneously, pain in the heart and lungs, we may presume that the affection is seated chiefly in the pneumo-gastric nerves; but where there is simply stricture of the heart, without pulmonary pain or difficulty of breathing, its site is in the nerves which the heart receives from the great sympathetic. But he supposes that other nerves may also be implicated at the same time, either by direct anastomosis or by sympathy; and that the branches of the bronchial plexus, particularly the cubital, are nearly always so affected. "The anterior thoracic originating in the superficial cervical plexus are, moreover, frequently implicated; and this is sometimes further the case with the branches derived from the lumbar and sacral plexuses, when the thigh and leg participate in the attack, which occasionally happens."

20. BRERA, ZECHINELLI, AVERARDI, and some others consider the disease to be occasioned by pressure of enlarged abdominal viscera on the heart, particularly of enlarged liver. JOSEPH FRANK conceives it to proceed from congestion of the cavities of the heart, occasioned by defective nourishment of its muscular structure; this defective nutrition itself resulting from previous inflammation, or from metastasis of gout or rheumatism, or from disease of the coronary arteries. (*Prax. Med. Univ. Præcep.*, t. ii. p. 260.) Respecting these, it may only be added, that the symptoms of angina pectoris are very seldom associated with enlargement of the abdominal viscera; and that, although they are much more frequently connected with the lesions alluded to by FRANK, this connection is by no means uniform, and is obviously not one of cause and effect; these lesions being rather coincident and partial results of the morbid state of the nerves, the altered sensibility of which constitutes one of the chief characteristics of the disease. It may be further stated, that Dr. DARWIN views it as a particular species of asthma, producing cramp of a peculiar kind in the diaphragm, or the other muscles of respiration; and Dr. BUTTER, while he conceives it to be of gouty origin, also refers it to the respiratory organs, particularly to the diaphragm. On these opinions it is unnecessary to comment.

21. Dr. CHAPMAN, to whose valuable paper I have already referred, states, "That the disease is a species of neuralgia, I am entirely persuaded, commencing for the most part in the pneumo-gastric nerve, and spreading in different directions, as other nerves may become involved. The derangement of the heart and other structures, with which it is sometimes associated, I hold to be coincidences or effects, and not the cause; since, among many reasons which might be adduced in corroboration of it, the disease has undoubtedly prevailed independently of such organic lesions, and, conversely, these have existed without occasioning it. But what is the immediate cause of the irritation of the nerves, inducing this neuralgic condition, giving rise to the subsequent phenomena of the disease? This is a question, which hitherto has not been clearly answered. My conviction is, that it is derived from irregular gout, which misplaced, thus operates as an irritant of the nerves, and probably first of those of the stomach."

22. It will be remarked from the foregoing, that JURINE, DESPORTES, LAENNEC, and CHAPMAN agree so far as to impute the disease to a species of neuralgia of the pulmonary and cardiac nerves, affecting the functions of the heart and respiratory organs, and extending by nervous connection to other parts; the organic lesions found in fatal cases being either coincidences, or effects of the disease; and after an attentive examination of the phenomena attendant on several cases of the affection which have come before me, I see no reason for differing materially from this opinion. With regard to the origin of this affection of the nerves in misplaced gout, I cannot so implicitly agree with Dr. CHAPMAN. The connection had been previously remarked by several physicians, as I have already stated, particularly by those whose names have been adduced, as well as by SCHMIDT and BURTON,—a circumstance favourable to the idea that it is founded in truth; and evidence of

it may even be found in Dr. MUSGRAVE's very excellent, but now scarcely ever noticed work, on Anomalous Gout. WICHMANN, however, has disputed this connection, and apparently with much reason. The notice which had been taken of this morbid relation is very candidly referred to by Dr. CHAPMAN, who has adduced the particulars of six cases in which this affection was evidently connected with gout, and in which recovery took place, after means had been successfully employed to invite this disease to the extremities. In the majority of those cases, the patients had never previously suffered a gouty attack, and yet the means employed were successful in causing it to appear in the lower extremities.

23. But whether this disease is merely a form of misplaced gout, or an affection *sui generis*, which, when occurring in persons of a gouty diathesis, the induction of the regular gouty paroxysm in the extremities generally removes, my experience does not enable me to decide. In two persons whom I was lately called to treat, and with whom I have been long acquainted, I have no reason to suspect a gouty tendency; but the connection so satisfactorily established by Dr. CHAPMAN is evidently by no means infrequent, and is one which ought never to be overlooked during treatment, for I have remarked it in several instances. I believe that, in addition to the nervous character of the malady, the substance of the heart is often weak, thin, pale, and attenuated, or even softened, or fatty, as if its substance were imperfectly and unhealthily nourished; and that its cavities, consequently, had become occasionally dilated and congested. This view is accordant with the treatment generally found most successful in removing the disease. In a great proportion of the cases before referred to (§ 10.), of which I had made notes, chiefly collected from authors, dissection had been made in about fifty of those which were fatal; and out of this number nearly forty presented some degree of disease of the heart or large vessels;—most frequently ossification of the valves, coronary arteries, and aorta; and fatty softening and emaciation of the heart. But whether these lesions are the consequence or the cause of the disease may be disputed. I believe they are the latter.

24. VI. The TREATMENT of this disease necessarily respects, 1st, the measures which may be adopted during the paroxysm; and, 2nd, those which should be resorted to in the intervals, with the view of effecting a perfect cure.

25. 1st, In respect of the means which may be employed during the fit, with the view of diminishing its duration and violence, no very precise or dogmatic direction ought to be given. Much will depend upon the peculiar characters of the case. The patient should always be placed in a state of tranquillity; and, particularly, if the countenance be pale, and the carotids pulsating feebly, in the supine or reclining position. The propriety of bleeding in the fit has been discussed by several physicians, and depends entirely upon the particular features of the attack. Where the symptoms are urgent, the patient plethoric or vigorous, or the pulse full and possessed of tone, there can be no doubt as to the propriety of the measure. Dr. READ (*Dub. Med. Trans.*, vol. i. p. 105.) has recorded a case which well illustrates the good effects of this treatment during the paroxysm. In

more questionable cases, where the pulse is weak, and the countenance is collapsed, bleeding from the arm ought not to be had recourse to. It is doubtful whether or not cupping even should be employed; but where this latter state is not extreme, and especially in cases of intermediate grades of severity, cupping between the shoulders, to a small or moderate extent, as the case may seem to require, will generally afford relief, particularly if used simultaneously with derivatives to the extremities.

26. But in nearly all cases, and still more particularly in those characterised by syncope, and an imperfect action of the heart, *frictions* with stimulating and irritating substances ought to be previously employed over the anterior parts of the thorax, and *stimulants* and *antispasmodics* exhibited internally. As to the extent and repetition of the blood-letting, whether general or local, the practitioner ought to be able to decide, being guided in this, as in other remedial means, by the apparent energies of the constitution, and the state of the vascular system; if these admit, and especially if signs of plethora, or of congestion of the cavities of the heart and large vessels of the chest, exist, the depletion may be carried to a considerable extent, or repeated, according to the relief obtained. The object here is to reduce the body to be moved to a nearer relation to the state of the moving power, at the same time that we endeavour to increase the energy of the latter.

27. I should add, that the propriety of bleeding, in the paroxysm particularly, has been much disputed, and especially by continental authors. Where the pulse is feeble and soft, and the action of the heart weak, it is generally inadmissible; but, wherever we entertain doubts respecting it, the external and internal use of stimulants and antispasmodics, with frictions, should be cautiously premised, and only local depletions adopted; or depletion of every kind should be entirely omitted until after the paroxysm, when either general or local blood-letting, according to the particular circumstances of the case, may be practised with necessary precautions. I have employed moderate blood-letting in three cases, in which the propriety of the measure seemed questionable, the patients being of spare habits of body, and weakened states of system; but every precaution was taken to prevent immediate ill effects from the operation. In one of the three relief was afforded; in another, the advantage was very doubtful; and, in the third, the disease was evidently exacerbated by it, although slight benefit seemed to result from it at the time. In one of those cases the serum of the blood had a milky appearance, from the presence of an oily matter, resulting from imperfect assimilation. From this evidence, therefore, I infer that, where there are no signs of vascular plethora or cardiac congestion, or where the vital energies of the patient are depressed, and we presume the substance of the heart is attenuated and imperfectly nourished, we should be extremely circumspect in having recourse to vascular depletions of any description, and should particularly avoid bleeding from a vein; but, at the same time, we should be equally careful not to administer too active stimulants.

28. Next to the employment of depletion, under the above restrictions, in suitable cases, and with the concomitant means recommended, the

bowels may be opened by a *purgative medicine*, combined with some warm *antispasmodic* and *carminative*, as ether, spiritus ammoniæ aromaticus, camphor, musk, castor, spiritus anisi, capsicum, &c.; and these may be given at intervals subsequently. I have seen much relief afforded by full doses of camphor with opium, or with hydrocyanic acid. In the slighter attacks, and where the state of the vascular system and constitutional energies render it prudent to withhold depletion, friction with stimulating liniments over the thorax and epigastrium, as the following—

No. 14. R. Linimenti Camphoræ Comp., Linim. Ammonia, aa ʒj; Tinct. Capsici ʒiij. M.—

the internal administration of antispasmodics, and the exhibition of a purgative medicine, will be sufficient to give some immediate relief. The following will generally fulfil the intention:—

No. 15. R. Infusi Valerianæ ʒxj; Spirit. Ammonia Fœtid. ʒss; Tinct. Castorei ʒss; Acidi Hydrocyanici, ℥ij. M. Fiat Haustus bis terve in die capiendus.

No. 16. R. Infusi Sennæ Comp. ʒjss; Tinct. Sennæ Comp. ʒij; Spirit. Ammon. Arom. ʒjss; Tinct. Cardamom. Comp. ʒj. M. Fiat Haustus statim sumendus, et repet. si sit occasio.

No. 17. R. Mist. Camphoræ ʒj; Liq. Ammon. Aet. ʒij; Spirit. Ether. Sulph. Comp. ʒj; Tinct. Camphoræ Comp. ʒj; Syrup. Papaveris ʒj. M.

29. *Emetics* have been spoken favourably of by Dr. GOOD (*Study of Med.*, t. i. p. 667.). In a case of great severity, in which vomiting occasionally occurred when the paroxysm was excited by taking food into the stomach, I was induced by this symptom to try the effect of an emetic during an attack; but no benefit was derived from it.

30. The employment of *derivatives* to the extremities, particularly the lower, is generally beneficial, and ought not to be omitted in the paroxysm, whether we adopt the opinion as to the gouty origin of the disease or not. *Stimulating pediluvia*, and *sinapisms* or *blisters*, with all the other measures employed under similar circumstances in irregular or misplaced gout, had the effect, in the six cases of the disease published by Dr. CHAPMAN, of inducing the regular gouty paroxysm, and of affording speedy relief. The *affusion of cold water* has been recommended by some authors, but it is a dangerous remedy in this disease. *Cold epithems* to the head have been mentioned by J. FRANK (*Prax. Med. Univers.*, part ii. p. 273.), as having been used with advantage; they seem less objectionable. A similar remark may be applied to the tepid affusion on the head.

31. 2d, *The means which may be employed during the intervals or remissions between the paroxysms* are either *general* or *topical*. With respect to the first of these, a most studious attention to avoid the exciting causes of the disease must be inculcated. Next to this, all existing disorder of the digestive organs should be attended to and removed; and the diet and regimen of the patient strictly laid down and enforced. As the powers of the digestive organs are generally diminished, and the bowels either costive or irregular, *vegetable bitters*, with an occasional alterative aperient, either given alone, or in combination with an antispasmodic or anodyne, will often prove beneficial. With the view of thus strengthening the digestive organs, and removing spasm, SCHÆFFER (*Volkskrankheiten*, Jun. 1807) recommended vegetable bitters with opium, musk, camphor, or assaictida, and ELSSNER prescribed the *hydrochlorate of ammonia* with Hoffmann's anodyne. *Sulphate of zinc*, re-

commended by PERKINS (*Mem. of Med. Soc. of Lond.*, v. iii.), in doses of a grain, with a quarter of a grain of opium, given twice a day, has a similar action; but it generally is necessary to give it more frequently, and to increase the doses. With the same view I have given the *hydrocyanic acid*, either simply, or combined with the oxide of zinc, forming a *cyanide of zinc*, and in one case particularly, with greater advantage than from any other means. I have reason to believe that the *cyanide of iron* will prove equally beneficial; but my experience of its effects is too imperfect as yet to allow me to speak decidedly as to its merits in this disease.

32. In a case which occurred to me many years since, I employed the *preparations of iron*, particularly the sesquioxide and sulphate, being led to adopt them by the neuralgic characters of the case, and certainly with apparent advantage; but local means were also in operation at the same time. Wherever we have reason to suppose that the heart is debilitated, imperfectly nourished, or attenuated, the employment of tonics, particularly bark, and the preparations of iron, either alone or with antispasmodics, is particularly indicated, with strict attention to diet and regimen. *Auscultation* will be of great service, by intimating to us the particular state of the heart, which must in a great measure regulate our practice.

33. In a case of the disease which came under my care in 1824, I prescribed the *nitrate of silver* triturated with a vegetable extract, as recommended by SEMENTINI. This substance was continued in increased doses, until it occasioned an eruption, resembling nettle-rash, on the skin, — an effect noticed by this physician. The relief afforded by it, after this eruption began to appear, was decided. The patient is at the present time in the enjoyment of tolerable health. At the period of my prescribing this substance, I conceived that its exhibition in this disease had originated with myself; but I subsequently found that it had been given in two cases of angina pectoris, with advantage, so long ago as thirty years, by Dr. CAPPE (*Duncan's Annals of Med.*, vol. iii.).

34. *Arsenic*, in the form of Fowler's solution, had been recommended in this disease by Dr. ALEXANDER (*Med. Comment.*, vol. xv. p. 373.), at a period antecedent to the introduction of the nitrate of silver into practice as an internal medicine; and subsequently by Sir G. BLANE, who gave it with advantage, combined with digitalis and mercury (*Med. Chir. Trans.*, vol. iv. p. 136.).

35. Besides these, preparations of *bark* and other vegetable tonics have been recommended, either alone, or in combination with antispasmodics and anodynes. The *hydrosulphuret of ammonia*, in gradually increased doses (from eight drops to thirty) twice or thrice daily. The different preparations of *valerian*, the *ammonio-sulphate of copper* and *sulphate of quinine*, have likewise been employed, and occasionally with decided advantage: from the last of these, combined with an anodyne, particularly with opium and camphor, I have observed much benefit to be derived. The following formulae may be employed.

No. 18. R. Infusi Rosæ Co. ʒj.; Quininæ Sulph. gr. j—ij.; Acidi Sulph. Arom. ℥x.; Spirit. Ether. Sulph. Comp. ʒj.; Tinct. Opii ℥xij. M. Fiat Haustus bis in die capiendus. Or.

No. 19. R. Extracti Anthemid. ʒij.; Quininæ Sulph. gr. xij.; Massæ Pilul. Galban. Comp. ʒj.; Camphoræ Subactæ, gr. xv.; Pulv. Capsici, ʒj.; Syrup. Papaveris,

q. s. Miscæ benè et divide in Pilulas xxiv., quarum capiat unam ad binas vel tres bis terve quotidie.

Having derived much advantage from the internal use of the *bi-borate of soda* in dyspeptic irritability of the alimentary canal, I was induced to employ it in a case of this disease which occurred to me a few years since, in doses of ten to twenty grains, given in the decoctum althææ. It produced some relief; but the case was of the greatest severity, and little benefit, at least of a permanent description, was derived from any means which were adopted, excepting from prussic acid.

36. *Mercurials* have received the sanction of BRERA. I have employed them in three cases, at first as an alterative; five grains of blue pill having been directed occasionally at bed-time, and subsequently so as to affect the mouth. In one of these the alterative dose had a beneficial effect upon the state of the stomach and bowels; but this was of short duration. When, however, pushed further, so as to affect the gums, great irritability of the system, fever, restlessness, and increased pain, anxiety, and sinking, were occasioned by it. In the other case, evidently connected with hepatic disorder, the blue pill was also at first given as an alterative on alternate nights. It affected the gums after a few doses, and afforded relief. It was now pushed with the intention of inducing salivation; and a somewhat violent effect was produced on the mouth, which was relieved upon exciting the salivary glands. Decided advantage was now procured; the bowels were kept open by means of a stomachic aperient, an issue inserted in one of the thighs, and change of air recommended. This patient perfectly recovered.

37. Where plethora exists, *blood-letting* in the intervals will be serviceable, with a light abstemious diet. When the paroxysms are apt to occur during the night, I have found an opiate given at bed-time, as recommended by Dr. HERBERDEN, of great service. In one case of this description I gave the *acetate of morphine*, in the dose of an eighth of a grain, but it occasioned such distressing feelings of sinking, and general depression of the powers of life, that stimulants were required; yet the same patient had experienced relief from opium combined with camphor. On one occasion I tried the effects of *iodine* in the form of the tincture; but although its use was adopted with great caution, seven drops only having been given three times a day, it occasioned an increase of all the symptoms, apparently owing to its irritating effects on the digestive mucous surface, and the idiosyncrasy of the patient. I may here notice the practices recommended by SCULSINGER (*Hufeland's Journ.*, vol. i. p. 57.), consisting in the exhibition, every two hours, of the extract of the *lactuca virosa*, in doses of two grains, with half a grain of *digitalis*. What effect may we expect from the use of *colchicum*? Where the disease seems to originate in gout, the colchicum might be tried; but its use would require great circumspection. In my opinion, it should only be given in combination with stimulants, or antispasmodics and tonics, the tinctura colchici composita being the most promising preparation of it in such a case.

38. Although the patient labouring under this disease is generally incapable of any, excepting the most gentle, exercise; yet this should be

taken under favourable circumstances; and change of air, particularly to healthy, dry, and elevated situations, should not be overlooked. It will generally be observed, that persons labouring under the worst form of the disease, incapable even of walking or sitting upright for any time, will bear well, and even be benefited by, rapid travelling in a carriage. This was first evinced to me by the ease of a gentleman of great scientific and literary attainments, residing for a time at Paris, where I was called to him in the summer of 1829. He was anxious to return to England, from a dread of dying abroad. He undertook the journey with me, and was better during it than either previously or subsequently. He has since taken long journeys, with similar advantage.

39. *Secondly*, Much benefit will be often received from *topical* means. Under this head *rubefacients, issues, and setons* deserve particular notice. The latter have been employed on the insides of the thighs by MACBRIDE and DARWIN. KREIGELSTEIN and WOLFF also have observed advantage to be derived from them, when inserted either in this or in other situations. I have resorted to a peculiar form of issue in several cases of this disease, and, upon the whole, with much benefit. In one case, however, it failed of having the least good effect.

40. The form of issue to which I allude, and for the knowledge of which I am indebted to my learned friend Dr. HUTCHINSON, is the bark of mezereon root, deprived of its external cuticle, and, after having been soaked for some time in a little water, placed upon the surface of the part from which we wish to procure a discharge. This bark should be confined to its place by means of adhesive plaster, spread on paper of larger dimensions than the part covered by the mezereon bark. The bark may be renewed every night, until it procures a copious discharge. In some cases the effect is produced in a single night, or in twenty-four hours. When the discharge becomes copious the bark may be renewed less frequently. The adhesive plaster serves both to keep the mezereon in its situation, and to retain the discharge, so as to preserve it from soiling the clothes. When it is abundant the plaster may be renewed, and the secretion removed, as its occasional acrimony often tends to heighten and to extend the irritation. In a severe and chronic case of this disease, which occurred to me in 1830, I employed this form of issue, and kept a surface of about four inches square over the left small ribs discharging as long as the patient would endure this treatment. The disease disappeared, and up to this time it has not returned. The advantages of this issue are, that the patient can manage it from the beginning with great ease; and it may be readily increased to any extent, and the discharge augmented, according to the exigencies of the case.

41. *Artificial eruptions, from the ointment or plaster of the potassio-tartrate of antimony*, have now usurped the place of setons and issues; but, from a very extensive experience of the former, both previous and subsequent to the publication of an article on them in the London Medical Repository for April 1822, I consider them of inferior efficacy in some diseases, and particularly in this, to the pea-issue, or the issue now described. It is singular that the advantages to be derived from the production of artificial pustulation, in the

treatment of various disorders, were so little known or appreciated until the appearance of Dr. JENNER'S pamphlet on the subject, since the practice had been recommended long previously in the Lectures of the second and third MONROS on Morbid Anatomy, as being frequently preferable to the use of blisters; and had been found serviceable by GOODWIN, AUTENRIETH, and KREIGELSTEIN, in this affection, in which it had been employed by them at the end of the last century. *Liniments with croton oil*, are equally serviceable and more immediate in their effects.

42. *Blisters*, either frequently repeated, or kept discharging for a longer or shorter period, have received the sanction of PERCIVAL and many others. But little benefit will be derived from them, unless they be used in the way now named. THUILENIUS recommends (*Med. und Chir. Bemerkungen*, i. p. 183.) repeated blisters applied between the shoulders. I agree with him in the selection of this place in preference to others for their application, as well as in the propriety of repeating them frequently. M. LAENNIC states that he has derived great advantage from *magnetism*, used in the following manner, both in alleviating the paroxysm, and in preventing its accession.—He applies “two strongly magnetised steel plates, of a line in thickness, of an oval shape, and bent so as to fit the part,—one to the left præcordial region, and the other exactly opposite, on the back, in such a manner that the magnetic current shall traverse the affected part.” (*Diseases of the Chest*, p. 705.)

43. When the affection is complicated with other diseases, particularly with organic lesions of the heart, or enlargement of the liver, the treatment should be modified accordingly. In order to ascertain the nature of such complications, auscultation may be resorted to; for, although it gives us no information respecting the simple disease, it often enables us to detect the lesions with which it is sometimes associated, and to direct our means of cure more appropriately, and with happier results, than we could otherwise do. When the substance of the heart is weakened or attenuated (§ 23.), tonics, particularly sulphate of quinine, sulphate of zinc, and the various preparations of iron, given in decided doses, are particularly indicated. In other cases, as well as when the liver is affected, issues are generally serviceable. When the disease is connected with enlargement, &c. of the liver, mercury is almost indispensable. In all cases, whether simple or complicated, attention to diet and regimen, a pure air, amusement without excitement, and an equable and contented state of mind, are not only requisite to recovery, but are also necessary to render it permanent.

ANTIPATHY. SYN. *Ἀντιπάθεια*, Gr. *Antipathia*, Lat. *Der Widerwille*, die *Antipathie*, Ger. *Antipathia*, Fr. *Antipatia*, *Aversione*, Ital. *Antipathia Sensilis*, et *A. Insensilis*, Good.

CLASSIF. — 4. Class; 4. Order (Good).
I. CLASS; IV. ORDER (Author).

1. DEFIN. *Internal horror and distress on the perception of particular objects, with great restlessness, or with fainting.*

2. This singular affection has merely been mentioned by CULLEN: it has, however, received more attention from SAUVAGES, LINNÆUS, VOGEL, PLOUQUET, PASSAMENT, and GOOD. The last named writer has needlessly divided it into two species — *sensile* and *insensile* antipathy; the former arising from objects or subjects which strike some one of the senses; the latter from the presence of an object, as soon as it comes within the sphere of some unknown influence, although unperceived by any of the senses.

3. There are numerous instances of singular antipathy on record; and most persons of observation have met with others in the course of their experience. The vulgar explain them generally by considering that the mother had experienced a fright from the objects of antipathy during the early months of pregnancy — and there are, no doubt, some facts which countenance the supposition. Thus, JAMES the FIRST could not endure the sight of a drawn sword — RIZIO was killed at the feet of Queen MARY when pregnant with him; and many other instances are mentioned by writers: but more frequently the persons themselves, who are thus affected, have experienced frights during the early months of infancy, or have had their minds early and indelibly impressed by certain subjects. PETER the Great had a fall from a bridge into the water, when an infant; and he could not afterwards endure to hear the rattling of a carriage passing over a bridge. Persons often retain the antipathy to the sight of crabs, lobsters, &c. which had been occasioned by fright from them in infancy or childhood. A man-servant in the author's family, advanced in life, had so great an antipathy to the sight of a mouse, that he would fly as fast as he was able from the place where one was seen; and become quite frantic at the sight. He stated that his mother, who likewise had an antipathy to mice, had been distressed by one thrown upon her when pregnant with him. Some persons cannot endure certain odours, from the faintness, or sickness, or sense of anxiety and distress they occasion. This appears to proceed from peculiar idiosyncrasy. I have likewise seen persons who could not touch certain smooth objects without feeling a peculiar shudder or horror, followed by faintness in some. This appears to arise from associations excited in susceptible or sensitive minds.

4. The most singular instances of antipathy are those which occur at the presence of objects unperceived by any of the senses, forming the *insensile* antipathy of Dr. GOOD. Thus, a cat concealed in a room has been known to produce a most indescribable distress or horror in a person

who has not perceived it by any one sense, and has been, in no other way, informed of its presence. Some singular idiosyncrasy, doubtless, exists in such cases. SAUVAGES conceives that an effluvia proceeds from the animal, which, combining with that emanating from the person thus affected, occasions the unpleasant sensations upon his peculiar organisation or idiosyncrasy. This is, perhaps, the only opinion that can be formed on the subject.

5. The TREATMENT to be adopted for the removal of antipathies consists chiefly of resolute endeavours to overcome the morbid impression, by gradually accustoming the mind to its influence. Indeed, this is the only remedy that can be resorted to. Its adoption, successfully or otherwise, will entirely depend upon the mental energy of the patient. But there cannot be a doubt, that all impressions, however unpleasant or distressing, may be ultimately overcome by repetition, and a firm resolution either to endure, or not to be affected by them. The following works will furnish some curious information on this subject, with much trifling, silly hypothesis, and irrelevant matter: —

ANUS. See RECTUM.

AORTA. SYN. *Arteria Magna*. *Aorte*, Fr. *Aorta*, die *grosse Schlagader*, *Hauptstamm aller Körperpulsadern*, Ger. ITS DISEASES.

1. This most important vessel is liable to all the lesions which have been noticed under the article ARTERIES. Some of them, however, when seated in this artery, are so important, particularly as respects their effects upon adjoining viscera, and their extremely dangerous consequences generally, that I propose to give a succinct account of them in this place. In doing this, I shall so far depart from the alphabetical arrangement, in respect of the subordinate heads of the subject, as may be requisite to the consideration of it in strict pathological order. Functional disorder, therefore, of this vessel will be first considered; next, inflammation; and, lastly, those lesions which usually result from inflammation, &c., as aneurism, constriction, obliteration of the vessel, &c.

2. I. NERVOUS PULSATION OF THE ABDOMINAL AORTA. — CLASSIF. II. CLASS; I. ORDER. — This is not an infrequent affection in weak, emaciated, and delicate persons, and particularly hysterical females. It is often associated with collections of air in the colon or stomach; and with accumulations of fecal matters or morbid secretions in the cœcum. It is also not infrequently consequent upon neglected dyspepsia.

3. i. The Symptoms are generally very characteristic of the nature of the complaint, and sufficiently serve to distinguish it from organic lesion of the vessel. The morbid pulsation is generally associated with nervous or hysterical symptoms, and is of a variable character. It is increased and diminished, sometimes without any evident cause,

but more frequently by mental or moral affection and emotions, or by constitutional causes. Disorders of the stomach, and irregularity of the uterine functions, also sometimes occasion or reproduce it; and I have observed it to follow upon the paroxysms of sinking or leipthymia, to which very delicate females are occasionally liable.

4. Upon pressing the stethoscope firmly over the aorta, the pulsation will be generally felt limited in extent, in its transverse or lateral direction, but it will be very perceptible in the course of the vessel from the bifurcation to the epigastrium. Instead of the gradual, steady, and strong motion or impulse attending aneurism, there is felt a vigorous and smart jerk; and the sound is either merely a slight whizzing, or is scarcely to be heard.

5. ii. The *Treatment* of nervous pulsation of the aorta will entirely depend upon the peculiar circumstances of the case in which it occurs. If the paroxysm is severe, the preparations of æther, asafœtida, valerian, and ammonia, should be exhibited. I have seen much benefit afforded by strong coffee and green tea in these cases. The dependence of the affection on mental emotions indicates the propriety of advising a tranquil state of mind and a mild diet, with attention to the regular functions of the bowels. In cases evincing much irritability, mental or corporeal, hyoscyamus, conium, or the acetate or sulphate of morphine, in very small doses, particularly hyoscyamus combined with camphor, will be found useful. The preparations of morphine, however, should be cautiously administered in this affection. In a case which occurred to me sometime ago, the sixteenth part of a grain only of the acetate of morphine was followed by unpleasant depression. Upon the whole, more advantage will accrue from the antispasmodics than from the sedatives just named; but in cases characterised by attendant irritability, the combination of substances belonging to both these classes of remedies will be of great service.

6. In all cases of this affection occurring in females, — and the great majority of them do occur in this sex, — the state of the menstrual discharge should receive the utmost attention. When the more distressing state of the affection subsides, a more tonic regimen and plan of cure may be adopted. The bitter infusions and decoctions, particularly those of calumba, cinchona, cascarrilla, and chamomile, with the alkaline preparations, &c., and subsequently the preparations of iron, the shower bath, cold salt water bathing, chalybeates, regular exercise in the open air, and light nutritious diet, are the means chiefly to be depended on. When associated with other ailments, it is generally symptomatic of them, and therefore in such cases the treatment must be directed to the primary complaint.

7. II. INFLAMMATION OF THE AORTA. — SYN. *Aortitis*. *Aortite*, Fr. *Die Aortenentzündung*, Ger. CLASSIF. II. CLASS; II. ORDER. — Inflammation of the aorta occasionally takes place, but more frequently in a chronic than an acute form, and commonly consecutively of inflammation of the internal surface of the heart, and during the course of certain states of fever. The internal membrane of the vessel is sometimes alone inflamed, particularly when the disease takes place during fevers, or extends to it from the internal surface of the heart's cavities; but, in several cases, the subjacent cellular tissue, or both it and the internal

membrane, are chiefly affected. Aortitis seldom originates in the exterior coats of the vessel.

8. i. The CAUSES of aortitis are, — 1st, External injuries, as blows, contusions, falls, &c.; 2d, Violent, or too long-continued exertion; 3d, The use of hot, stimulating, and acid ingesta, spirituous liquors, and the introduction, by absorption or otherwise, of irritating poisons and morbid secretions, &c. into the circulation; 4th, The extension of inflammation from the heart, lungs, pleura, and pericardium, and the suppression of the eruption in eruptive fevers; — M. PORTAL states (*Anat. Med.*, t. iii. p. 157.) that he has met with it in cases of this description; — and, 5th, The causes which are productive of diseases of the heart.

9. ii. The SYMPTOMS can scarcely be stated with any hopes of enabling the practitioner to distinguish this disease, which is generally met with in conjunction with other maladies; particularly fevers, and inflammations of the heart, lungs, pericardium, and pleura, and disclosed to us only by *post mortem* examination. — a. When inflammation more or less acute extends along the descending aorta, the patient generally complains of a smarting and painful sensation in the direction of the spine, with a violent feeling of pulsation of the aorta; extending to the iliacs, without any appearance of enlargement or tumour; and unaccompanied by smallness of pulse in the remoter arteries, particularly those of the superior parts and extremities of the body. In the more acute cases, a sensation of heat is felt in the region of the vessel, sometimes with oppressive anxiety, leipthymia, or tendency to fainting, and always increased force and vivacity of the pulsations of the vessel.

10. b. The *chronic* states of this disease admit not of recognition until they have produced some one of those organic lesions, which occasion marked obstruction of the circulation, or aneurismal dilatations. Dyspnoea upon slight exertion, emaciation, a pale yellowish tint of countenance, palpitations, hypertrophy and dilatation of the heart's cavities, œdema of the extremities, &c., are then the usual symptoms; and, although they furnish no certain evidence of the existence of this disease, yet when they are present, without the signs of narrowing of, or obstruction in, the orifices of the heart's cavities, and of the origin of the aorta, chronic disease of the aorta may be presumed to exist.

11. c. Aortitis, particularly in its chronic states, is occasionally complicated with hypertrophy of the left ventricle; the hypertrophy either causing the inflammation of the aorta, or the latter occasioning the former, particularly when the canal of the vessel is narrowed or obstructed by the effects of the inflammation. The other complications have been already noticed (§ 7—9.). It is chiefly owing to the more frequent occurrence of the disease in a complicated than in a simple form, that it is so commonly overlooked, and so difficult to be ascertained even when its existence is suspected.

12. iii. The PROGNOSIS of this disease, when its existence is presumed, is always unfavourable; on account both of our ignorance of much that is important respecting its symptoms, complications, and consequences, and of the fatal nature, sooner or later, of a great part of the effects to which it gives rise.

13. iv. The LESIONS produced by inflammation of the aorta are nearly the same as those I have enumerated in the article on the lesions of arteries. But as these changes, when affecting this important

vessel, are often the first step to the formation of aneurism in it, I shall here briefly allude to them as they actually appear upon examination. *Aortitis*, whether occurring simply, or with disease of the heart or other related viscera, presents the results of various grades of activity. In the more acute cases, the internal surface of the vessel is of a deep or dark red, sometimes approaching to purple; and both the internal membrane and the middle coat are easily torn. The connecting cellular structure and the fibrous coat are much more injected with blood than natural; and coagula, more or less firm, and of a fibrous character, sometimes adhere to the internal surface of the inflamed part: but this is not often observed in the aorta, as the current of the circulation through it seems to wash away the fluid as soon as it is effused, and before it coagulates on the surface which produced it. *Obliteration* of the aorta (see § 53.) may, however, arise either from external pressure, or from false membranes formed in its internal surface, so as to obstruct the current of the circulation in it; or from depositions of lymph between its coats, sufficient to produce the same effect, the obliteration being thus a remote consequence of the obstruction.

14. The results of chronic aortitis, are more frequently met with than those of the acute. These are yellow spots, or yellow curdy matter deposited under the inner membrane, which may burst from the distention and the friability occasioned by the inflammatory state; the curdy matter projecting like a tubercle into the canal of the vessel; bony deposits, which are also just formed under the internal membrane, and in like manner become exposed and washed by the current of the blood in the vessel; thickening and induration of the coats of the aorta; friability and softening of one or more of them; ulceration commencing in the lining membrane, and extending more or less through the exterior tunics, till at last dilatation of the external coats in the form of a pouch, or fatal hæmorrhage, ensues; and cracking, and laceration or dilatation, which, with the former lesions, generally originate the different forms of *aneurism* to which this vessel is liable (see § 18.). In a case which occurred to Dr. J. Wilson in the Middlesex Hospital, the internal surface of the ascending aorta and the arch was extensively ulcerated, without dilatation.

15. Dilatation of the coats of the aorta may first occur, and then the inner or middle coats give way when it has reached a certain pitch: or the laceration of the inner coats, with or without previous ulceration, may take place previous to the dilatation. But either state of disease—dilatation or laceration—(especially the latter, seems to proceed from a nearly similar pre-existing change of the internal tunics, one evidently connected with slow inflammatory action. Even dilatation, which has been attributed to debility of structure, is more frequently a result of inflammation, which in fact occasions here, as it does everywhere else, debility of structure; defective vital cohesion of the texture being a general result of inflammation.

16. v. TREATMENT. Aortitis requires the same treatment as other acute inflammations. General and local blood-letting, perfect repose, both moral and physical, and the rest of the antiphlogistic regimen are indispensable. The preparations of *digitalis* in order to quiet the heart's action, cooling

aperients to remove fecal accumulations, and counter irritants to elicit a determination of the fluids to external parts, are amongst the most efficacious means. In resorting to counter-irritation, care should be had not to employ substances calculated to excite general irritation by their use in this way. The ointments or liniments of the potassio-tartrate of antimony (see F. 305. 749.) are the only means of this description; excepting issues, which should be used in this disease.

17. When those symptoms appear which have been stated to result from *chronic aortitis*, or its effects, local depletions,—particularly when signs of congestion of either the heart, lungs, or head, appear,—a restricted diet and regimen, perfect repose of body and mind, attention to the abdominal functions, and the use of the tartarised antimonial ointment, or setons or issues, are the chief means that can be called to our aid. Other remedies may, however, be employed, with the view of alleviating or removing the contingent symptoms and ailments that may supervene.

18. III. ANEURISM OF THE AORTA. — *Aorten-rysuma*. — *Die Aortenweiteung*, Ger. — CLASSIF. IV. CLASS; II. ORDER.—i. Aneurism of the aorta is a not infrequent consequence of inflammation, particularly of its more chronic forms. The changes in the parietes of the vessel, constituting aneurism of it, are the following:—1st, *Simple dilatation* of the whole circumference of the vessel; 2d, *Dilatation* of one side only, in a sacculated form, without rupture of its coats, or *true aneurism*; 3d, *Dilatation* of the external or cellular coat of the vessel, occasioned by rupture or ulceration of the internal and middle coats, or *consecutive* or *false aneurism*; and, 4th, *Ulceration* or rupture of the internal coats taking place after their dilatation, and occasioning the still further dilatation of the cellular coat, constituting *mixed* or *compound aneurism*.

19. A. *Simple dilatation* of the whole circumference of the aorta may occur to a greater or less extent along the vessel; it may be limited to a small portion only; or it may occur in several parts, giving the vessel an irregular shape, and forming several oval expansions of it. The second of these is the most common. The dilatation is various in extent; it is frequently as great as twice or thrice the natural calibre of the vessel, or even greater. It is usually more evident in one side than in another, and is attended with some one or more of the organic changes described as consequent upon chronic inflammation of the aorta (see § 13—15., and ARTERIES, *Pathology of*), particularly thinning and thickening of the coats, thereby resembling passive and active aneurisms of the cavities of the heart. The situations in which this change of diameter of the vessel occurs most frequently, are the ascending portion and arch; but it is not infrequent in the descending aorta. Dilatation of the pulmonary artery is very rare. This simplest form of aneurism, although frequently accompanied with various morbid depositions in the coats of the vessel, never contains laminated coagula, unless the lateral dilatations very nearly approach the state of sacs or pouches, constituting the next variety. In some cases of this form of aortic aneurism, similar changes are also met with in some of the large arterial trunks, as the subclavian, cœliac, and iliac arteries.

20. B. *True aneurism*, or extensive dilatation of a portion of the circumference of the aorta, fre-

quently has a neck of less diameter than the body of the sac. It seems to arise from a loss of elasticity and vital resistance of the portion of the vessel thus affected, in consequence of chronic inflammation and its effects. Owing to this cause the dilated portion of the vessel often presents many of the lesions described as consecutive of the inflammatory state, particularly reddened spots, minute fissures, atheromatous, cartilaginous, or ossific deposits, &c. This variety most commonly affects the ascending portion and arch of the aorta, and shoots out from its anterior or lateral parts. It often attains a considerable size, being sometimes as large or larger than the fetal heart, and generally inclines toward the right side of the chest. The dilated coats of the vessel are generally thicker, and but very rarely thinner than natural, unless in parts of the aneurismal pouch. When it arises from the root of the aorta, and the inner and middle coats burst, fatal extravasation takes place within the pericardium; no false aneurism taking place in this situation, owing to this part of the vessel being destitute of the cellular coat. Coagula do not frequently form in true aneurism as long as the current of blood in the sac continues to be not much obstructed; but when, owing to the narrowness of its mouth, or to retardation of the current of circulation in it, a partial stagnation takes place, coagula then form, frequently in an irregular or confused state, but sometimes in regular layers.

21. *C. Aneurism with ulceration of the internal coats, or false aneurism.* This variety arises, 1st, from rupture or fissures of the internal coats, owing to a loss of their vital cohesion, and to friability consequent upon chronic inflammation, associated with fungous, calcareous, and steatomatous deposits; and is often occasioned by accidents, or violent or sudden extension of the vessel; 2d, from ulceration following scrofulous and chronic inflammations, and the detachment of various depositions formed in the internal membrane. Cases have been recorded by LAENNEC and GUTHRIE, wherein fissures of the internal coats of the vessel, instead of producing aneurismal dilatation of the external coat, had dissected it from the fibrous tunic along the greater part of the length of the vessel; but such occurrences are very rare. This variety of aneurism cannot be formed at the commencement of the aorta; it is most frequently met with in the descending aorta, and the part opposite to the tumour or sac is generally not in the least dilated. Numerous instances of this variety of aneurism are recorded by modern authors.

22. *D. Mixed or compound aneurism.* After all the coats of the vessel have been dilated to a certain extent, forming either simple expansion or true aneurism, but, owing to the less extensible properties of the internal coats, conjoined with the effects of previous or existing inflammatory action, rupture or ulceration of them takes place, the impulse of the current of the circulation dilates still further the yielding cellular coat of the vessel, and a sac or cyst is thus not infrequently formed of this coat surmounting the primary aneurism. In this case the perforated internal coats form the neck of the cyst, which is always narrower than the cyst itself. When the ruptured part of the internal coats is considerable, so that the impulse from the current of blood prevents its

coagulation in this cyst; or, when in this, as in the other varieties of aneurism, coagulable lymph is not formed, so as to give rise to layers of fibrinous coagula within the sac calculated to support it, rupture of the sac will sometimes occur, and a diffused form of aneurism be the result.

23. *E. Of certain changes connected with aneurism of the aorta.* In some rare instances an aneurism of this vessel has been observed by HALLER, DUBOIS, DUPUYTREN, and LAENNEC, consisting of hernia of the inner coat through the ruptured fibrous coat. But it is obvious that aneurism, or tumours of this description, can seldom reach any considerable size without being either ruptured, owing to the more friable nature of the internal membrane, or confined by granulations and adhesions on its external surface, as shown by the experiments of HUNTER, SCARPA, and HOME. Solid small tumours, of the size of nuts, and closely attached to the aorta, have been described by CORVISART and HODGSON; the latter of whom supposes, with LAENNEC and BERTIN, that they are the remains of spontaneously cured aneurisms, their sacs having been filled with coagula, and their size afterwards diminished by absorption. The deficiency of the coats of the vessel, at their points of union with it, seems to confirm this opinion.

24. *a.* One of the most important changes connected with this disease is the deposition of fibrine and the formation of coagula on the internal surface of the sac. This process generally appears to proceed by progressive steps: and the deposition thus presents successive layers. The most central of these generally consists of blood only, more or less firmly coagulated; and each layer becomes firmer, drier, and paler, and more and more fibrous, until the parietes of the sac is reached. In many cases, the most external layers chiefly consist of a whitish or greyish yellow fibrine, more or less opaque and friable. Sometimes they nearly resemble dried paste. The more recently formed coagula are soft, loose, and often only partially adherent to the layer next it. In some cases, blood seems infiltrated between the layers. Those next the vessel are generally united to it by a fine cellular-like tissue, furnishing appearances of a partial organisation. These depositions evidently proceed from the effusion of coagulable lymph from the internal surface of the aneurismal sac, and the partial stagnation or retardation of the blood, favoured by the narrowness of the neck of the sac, and the inflamed, uneven, or rugged state of its internal surface. When neither of these states exists, as is often the case in respect of the first two varieties of the disease, and particularly when the neck of the pouch is wide, neither coagula nor layers of fibrinous deposits are formed. When, however, inflammation of the internal surface of the dilated vessel or of the sac exists, and when a morbid secretion takes place from it, this will originate coagulation of a portion of the blood which comes in contact with it, and form, at the same time, a bond of union between the coagululum and the internal surface of the dilated coats of the vessel. The thickness and compactness of the coagula in aortic aneurisms are often remarkably great, and are chiefly to be imputed to this mode of origin. (See art. BLOOD.)

25. *b.* As the aneurismal tumour enlarges, it

generally occasions important changes both in itself and in adjoining parts. Those which respect the sac itself are chiefly thickening of the dilated coats, or thinning of them; and, in some instances, of both these changes in the same case. When the extension of the sac is considerable, or when moderate, if opposed by a firm substance, as cartilage or bone, ulceration or absorption of the parietes of the sac, inflammation of its more exterior parts and adhesion to adjoining structures; and, ultimately, as the tumour increases, perforation or rupture of the more prominent part, followed by fatal hæmorrhage, take place. The mode in which the aneurism bursts is different, according to its situation and the structure which it compresses and destroys; thus it not unfrequently breaks by ulceration and perforation of a limited part of the sac. In some cases, particularly when it opens into a serous cavity, distinct laceration of the more exterior covering occurs; when it reaches a mucous surface or the skin, a slough is formed on its most prominent part, which is soon detached, and fatal hæmorrhage is the result. In the majority of such cases, the proper coats of the vessel may have been long previously destroyed at one part or other of the sac. But, if the aneurism form at the root of the aorta, rupture or ulceration of the proper coats of the vessel is followed by instant effusion of blood into the pericardium. Rupture of the aneurismal tumour, as respects the coats of the vessel, whether bursting into a hollow cavity or upon a surface, or forming a diffused aneurism, is generally transverse; but it is, in some cases, longitudinal, when it implicates all the coats of the vessel; or the rupture of the internal coats is transverse, and that of the external coat longitudinal; the former being almost universally transverse. The effects of aneurism upon adjoining parts require particular notice.

26. *F.* Of the effects of aortal aneurisms on adjoining parts, and the situations in which they break. The effects of aneurisms on adjoining parts necessarily depend upon their volume, firmness, and position. The heart, lungs, trachea, large bronchi, œsophagus, pulmonary artery, large veins, thoracic duct, and various organs contained in the abdominal cavity, may be displaced, atrophied, or partially destroyed, by the compression occasioned by them.

27. *a.* The vena cava is not infrequently more or less obstructed by the pressure of aortal aneurisms. M. REYNAUD (*Journ. Hebdom.* t. ii. p. 109.) met with a case in which this vessel was very nearly obliterated by an aortal aneurism, and M. BOUILLAUD mentions a case in which the superior vena cava was so much compressed by an aneurism at the arch of the aorta, that apoplexy was caused by it (*Dict. de Méd., et Chir. Prat.*, t. iii. p. 403.); and COUVSART (*Journ. de Méd. par MM. Couvart, &c.*, t. iii. p. 85.) and BERTIN, relate similar instances. The thoracic duct has also been destroyed by it, as was observed by M. LAENNEC. Mr. HODGSON and Sir A. COOPER met with cases in which the common carotid and subclavian arteries were completely obliterated by the pressure of aortal aneurism.

28. *b.* When the pressure of an aortal aneurism destroys an adjoining viscus or structure, the ulcerative inflammation is often extended from the parietes of the sac to them, followed by the adhesion and absorption or ulceration of the parts

most compressed, until the tumour bursts, in one of the modes now stated (§ 25.), into one or other of the following situations:—Aneurism of the ascending or pericardial aorta generally opens into the pericardium: in three cases it bursts into the pulmonary artery, recorded by Dr. WELLS (*Trans. of Society for Impr. of Med. and Chirurg. Knowledge*, vol. iii. p. 85.), M. SUE (*Journ. de Méd. Contin.*, t. xxiv. p. 124.), and MM. PAYEN and ZEINK (*Bul. de Fac. de Méd.*, No. 3. 1819). Aneurism of the arch of the aorta may break into the trachea, œsophagus, pleural cavity, or into the pericardium. That of the descending aorta generally bursts into the pleura, œsophagus, posterior mediastinum, or into the lungs. Aneurisms of the pectoral aorta most frequently burst into the left pleura; they have, however, been known, but in two instances only,—recorded by M. LAENNEC and Mr. CHANDLER,—to open into the spinal canal, having destroyed the bodies of the vertebræ, which are generally more or less injured in cases of aortal aneurism of considerable size. When seated in the ascending aorta, they often destroy the sternum; in both cases causing interstitial absorption of the bone, and often of the parietes of the sac and fibrous layers of coagula in contact with it, so that the blood washes the bone itself. The cartilages usually resist the pressure of aneurisms, either altogether, or much longer than the bones; and when the periosteum is inflamed by the pressure of the aneurism, an ossific deposit is not infrequently formed around the tumour.

29. *c.* Aneurism of the aorta may, however, destroy life, even without breaking in any of the above directions; either by impeding the action of the heart and displacing it, or by compressing the organs of respiration, or by occasioning congestion, infiltration, and hepatization of the lungs; or by compressing the œsophagus, or injuring some of the thoracic ganglia; or it may destroy or compress the thoracic duct and large veins, as stated above (§ 27.), to a fatal extent.

30. *d.* The bursting of an aneurism of the aorta is not necessarily followed by instant death, as has been shown by MM. LAENNEC and MARJOLIN, and very recently by Mr. S. COOPER. In a case read by this very able surgeon, at the Medico-Chirurgical Society, where the aortal aneurism had pointed under the left shoulder-blade, but subsequently broke into the œsophagus, several pounds of blood were discharged by vomiting and stool, yet the patient lived for many months afterwards, and pursued a laborious occupation; a second hæmorrhage at last proving fatal. When the sac of an aortal aneurism bursts, and the blood flows into a cavity or viscus, from which it is readily discharged, death usually is soon produced. But when the opening in the sac is so situated that the blood is effused into the cellular structure, and what was before a true or encysted abscess becomes a diffused one, life may be prolonged for some days or weeks, or even longer. This, however, will depend upon the situation in which the rupture takes place, and the nature of the parts into or upon which the blood is effused. When the sac of an aneurism is ruptured, the laceration is generally in the same axis, or nearly so, with the opening into the sac, owing to the impulse being greatest in this direction, unless a divergence is occasioned by

the unyielding nature of the parts in this situation, and by the slight resistance opposed by parts immediately adjoining.

31. *G. Of the causes of aneurism of the aorta.* Diseases of arteries, and consequently aneurism, are much more frequent in men than in women. Mr. HODGSON states that of sixty-three cases of aneurism, external as well as internal, seen by him, only seven were in females. But the proportion of cases of aortal aneurism met with in females is certainly much larger than this. I have seen three cases of aortal aneurism in females; but I have certainly not seen nearly twenty-four cases in males, which is the proportion here indicated. Syphilis and the use of mercury have been considered predisposing causes of aortal aneurism, but upon no just grounds. I am inclined to believe, with Mr. GUTHRIE, that the habitual use of ardent spirits has a more marked predisposing effect than any other cause with which we are acquainted. A more immediate state of disposition is created in the vessel itself by inflammatory irritation of its parietes, and the consequent diminution of its elasticity and vital cohesion, or power of resistance opposed to the casually augmented impulses of the heart, especially during mental excitement and corporeal exertion. Hypertrophy of the left ventricle, particularly if consequent upon chronic inflammation of the vessel, and influenced by moral and physical causes, will tend to produce dilatation or rupture of the coats of the aorta. The most frequent exciting causes undoubtedly are excessive mental emotions, and violent exertion, particularly of the trunk of the body, and when suddenly made; but it seems evident that a morbid state of the vessel has existed previously, at least in the majority of such cases.

32. ii. *Of the symptoms and diagnosis of aortal aneurism.* These naturally divide themselves into, — 1st, the rational or general signs; and, 2d, those which are detected by auscultation.

a. *The rational symptoms of aneurism of the aorta,* whilst the tumour still remains concealed in the large cavities, are very equivocal. The effects produced by it also proceed from various other diseases. Those symptoms, even when considered collectively, are extremely fallacious; but when viewed in connection with those which are detected by auscultation, they are very important aids to diagnosis. 1st, Aneurism of the *pectoral aorta* occasions a sense of oppression or infarction in the chest; but this is felt in various diseases of the thoracic viscera. Dissimilarity of the pulse in both wrists is sometimes present; but this is also met with from diseases of the subclavian artery, from tumours pressing upon it, or from an irregularity in the distribution of the brachial or radial arteries. A *purring tremor*, as pointed out by CORVISART, is sometimes perceptible when the hand is placed upon the middle and upper part of the sternum: when distinctly felt, it indicates aneurism of the ascending aorta: it is also felt above the clavicles in aneurism of the arch, and is one of the surest symptoms of the first and second varieties of the disease; but it is often indistinct when the aneurism is sacculated and contains layers of coagula. This tremor, however, sometimes proceeds from other causes than aneurism, more particularly from the mucous rattle seated in the large bron-

chi; but, in this case, the purring tremor is not so constant or continued as in aneurism.

33. Pressure from this disease on the trachea and large bronchi occasions a wheezing or sibilous respiration, which is generally permanent, referable to the lowest part of the throat, and sometimes with a whispering or croaking voice; the breathing is also anxious and laborious. Pressure of the tumour on the œsophagus renders deglutition of solids difficult and acutely painful or lancinating, and sometimes even impracticable. But these effects upon the function of respiration will be produced by various diseases of the larynx, and by frequent accumulations of viscid mucus in the upper part of the trachea. The attentive observer will, however, readily ascertain the existence of these affections. Other tumours may also exist and occasion similar symptoms both of respiration and of deglutition; but, in such cases, the diagnosis is often impossible.

34. When the aneurism has eroded any of the bodies of the vertebra, a gnawing or boring pain is felt in the spine; and, when the tumour affects the brachial plexus of nerves, an aching of the left shoulder, extending to the neck and scapula, with impaired power, formation, and numbness of the arm is complained of. Rheumatism of the shoulder-joint, or parts adjoining, and severe spinal disease, are often attended with similar sensations; and the symptoms referred to the shoulder and arm are frequently present in pericarditis, organic diseases of the heart, and angina pectoris, from the ramification of branches of nerves from the cardiac ganglia to the brachial plexus.

35. Pulsation felt beneath the sternum, or ribs, at the upper part of the thorax, is amongst the most certain signs of this disease: but we should recollect that it will also be occasioned by any tumour interposed between the thoracic parietes and the aorta, and in contact with the latter; by adhesions of the pericardium to the heart and effusions of fluid into the former, and by considerable enlargement or dilatation of the heart itself. Pulsation above the clavicles, although a frequent symptom of aneurism of the ascending aorta or of its arch, may likewise proceed from other causes, as enlarged glands, or various kinds of tumours, receiving the impulse of the subclavian arteries; from subclavian aneurism, and aneurisms of the innominate and common carotid, between which and aortal aneurism the diagnosis is most difficult, as BURNS, COOPER, MONRO, and HODGSON have pointed out. Violent pulsations of the carotids have been adduced as a sign of aortal aneurism; but they may arise from nervous affection of the heart, hypertrophy of the left ventricle, or from obstruction of the flow of blood in the descending aorta, or in the subclavian arteries.

36. When aneurism of the ascending aorta attains a certain size, a tumour is usually formed about the fifth and sixth ribs of the right side: when seated in the anterior part of the arch, it appears at the third and fourth ribs of the same side, at their sternal extremities, when in the upper part of the arch, the tumour rises above the sternum and sternal ends of the clavicles. When aneurism is seated in the descending thoracic aorta, and in the lower part contained in the thorax, it often points, after destroying the ribs and bodies

of the vertebræ, under the left shoulder-blade, and pushes out this part. The strong pulsations always present in the tumour indicate its nature. Notwithstanding, it may subside, or altogether disappear for a time under an appropriate treatment. Previous to the appearance of the tumour the symptoms are, as already shown, extremely fallacious.

37. In the advanced stages of aneurism of the thoracic aorta there are generally coughs with mucous or bloody expectoration, dyspnœa, and even orthopnœa, dysphagia, attacks of spasmodic suffocation, pain in the left shoulder, axilla, inner side of the arm, and ascending up the left side of the neck, with pricking pains in the tumour, and sometimes with a sense of whizzing or rushing at the top of, or under the sternum, and occasionally sensible to the hand. A dragging downwards of the larynx is sometimes complained of. All febrile symptoms are generally absent. Although these are the rational symptoms which are most to be depended upon, they must be viewed with those reservations which I have particularised in the preceding paragraphs.

38. 2d, When the aneurism is seated in the abdominal aorta, acute pain is complained of in the lumbar region, occasionally shooting into either hypochondria, and downwards into the thighs and scrotum. It is generally constant, but is also sometimes intermittent. It is often exacerbated into violent paroxysms, being dull and fixed in the intervals. It is aggravated by constipation, change of position, or pressure on the loins, and is unattended by any sense of heat in the part. In some cases there is also numbness of the lower limbs, as in that recorded by Mr. MAYO (*Med. Gaz.*, April, 1829), where the aneurism was situated between the crura of the diaphragm, and the dorsal pains were excruciating. The patient often complains of severe fits of colic, accompanied with spasm of the abdominal muscles, and occasionally there are nausea and irritation of the stomach, but with little loss of appetite. Constipation is always present. Decubitus on the left side or back often produces great distress, and occasions palpitation, which generally subsides upon turning on the face or right side. Coldness, formation, pricking, and numbness of the lower extremities, are not infrequent; and in some cases paraplegia has occurred, with involuntary evacuations of the urine and fæces.

39. The tumour may not become perceptible externally; but as it increases it will press injuriously upon, and sometimes displace, one or other of the abdominal viscera, particularly the stomach, liver, and even the heart. When the tumour can be detected externally, it has generally been on the left side, nearly on a level with the last dorsal vertebra. When large, it often impedes the action of the diaphragm, and thus deranges the respiration. In some cases it has pressed upon the pericardium, and thus had the double pulsation of the heart communicated to it. (See Cases by Drs. GRAVES and STOKES, *Dub. Hosp. Reports*, vol. v. p. 24.)

40. *b. Signs furnished by auscultation.* Dullness of sound upon *percussion* of the upper sternal portion of the chest and cartilages of the right ribs, although present in aneurism of the *pectoral aorta*, also occurs in other lesions of the thoracic

viscera. Dr. ELLIOTSON states, that a thrilling sensation given to the hand only, or chiefly, when applied *above*, or to the right of the cardiac region, and a bellows-sound heard in the same situation, may justly give a strong suspicion of the disease, but that neither the bellows-sound nor the thrill, always occurs. In four cases out of seven he found both wanting. LAENNEC never observed the thrill before the tumour became visible externally. He considers that the chief diagnostic of aortal aneurism is a strong and single pulsation, discernible by the ear in the situation of the aneurism, synchronous with the pulse at the wrist, stronger and louder than the action of the ventricles, and unaccompanied by the sound of the auricles. When, however, the aneurism comes in contact with the pericardium, a double instead of a single pulsation of the heart is communicated to the tumour. This was remarked in the cases recorded by M. CRUVEILLIER, and Drs. GRAVES and STOKES.

41. Dr. HOPE observes, that it is unimportant whether the pulsations be *single* or *double*; for, though the latter, may be distinguished from the beating of the heart by unequivocal criteria, viz.:—“1st. The *first* aneurismal sound coinciding with the pulse, is invariably louder than the healthy ventricular sound, and generally than the most considerable bellows-murmurs of the ventricles.—2d, On exploring the aneurismal sound from its source towards the region of the heart, it is found to decrease progressively, until it either becomes totally inaudible, or is lost in the predominance of the ventricular sound. Now, if the sound emanated from the heart alone, instead of decreasing it would increase on approximating towards the præcordial region.—3d, The *second* sound actually does sustain this progressive augmentation on advancing towards the heart; and as its nature and rhythm are found to be precisely similar to those of the ventricular diastole heard in the præcordial region, it is distinctly identified as the diastolic sound.* The second sound, therefore, corroborates rather than invalidates the evidence of aneurism afforded by the first; for, if both sounds proceeded from the heart, both would, on approximating towards or receding from it, sustain the same progressive changes of intensity.” (*Diseases of the Heart and Great Vessels*, p. 425.) Besides these views, with which I concur, the sound of the aneurismal pulsation is deep, hoarse, and of short duration, commencing and terminating abruptly, louder than the loudest bellows-murmurs of the heart, and of a rasping or grating character.

42. The sound of aortal aneurisms is generally audible in the back; and, when the descending aorta is the seat, it is louder in this situation than on the breast. If it presents the abrupt, rasping character, when heard on the back, the evidence of aneurism is complete; for, as Dr. HOPE observes, the loudest sounds of the heart, when heard in this situation, are so softened and subdued by the distance as totally to lose their harshness. This is in accordance with the opinion of M. BERTIN, who very correctly observes, that when the stethoscope is applied upon the sternum in aneurism of the substernal aorta, and on the

* See ARTS. AUSCULTATION and HEART, as to the sounds of this organ.

back, near the pectoral spine in aneurism of the descending aorta, the disease may be recognised, before any external tumour is seen, by a strong single sound, of greater intensity than that of the heart. The pulsations of aneurismal tumours of large arteries are indeed so intense, hoarse, sharp, and peculiar, as to be readily recognised by a person who has once examined them with the stethoscope, although the sounds they furnish cannot be readily described.

43. The *purring tremor*, already noticed as felt by the hand, may also be ascertained by the aid of the stethoscope. It is chiefly found above the clavicles, in cases of simple dilatation of the ascending aorta and arch and sacculated aneurism in the same situations. In old and large aneurisms, containing layers of coagula, it is generally absent, and is more intense the more unequal and rugged the interior of the diseased portion of the vessel, particularly when it is studded with osseous or cretaceous deposits. Dr. ELLIOTSON states, that when the aneurism is large, a single, and more frequently a double, bellows-sound is often heard in the seat of aneurism, distinct from the beating of the heart: when the sound is double, the first is heard along with the pulse, the latter, often the louder of the two, afterwards. The bellows-sound in these cases may be ascribed to the passage of the blood from the dilated aneurism into the narrower commencement of the healthy vessel; and, when the sound is double, the second may proceed from the reaction of the dilated part of the vessel impelling a portion of the blood into the narrow and healthy vessel after the action of the left ventricle.

44. 2d, Aneurism of the *abdominal aorta* is more easily detected by auscultation than aneurism seated within the chest. A constant and powerful pulsation is felt by the hand, and still more remarkably by the ear resting on the stethoscope, accompanied with a brief, loud, and abrupt bellows-sound; but not so hoarse as that of aneurisms in the chest. The pulsation is *single*, unless the tumour comes in contact with the diaphragm and pericardium; and it is either inaudible or very indistinctly heard in the back. By pressing the instrument in various directions, so as to bring it as close as possible to the tumour, its seat and dimensions will be ascertained.

45. iii. TREATMENT.—The method of cure first recommended by VALSALVA has been since very generally adopted, not only in aneurisms of the aorta, but also in similar diseases of arterial trunks. I believe, however, that it has been often carried to a very hurtful length. I have seen cases in which aneurismal tumours had existed for a long time without any increase, as long as the patient avoided any marked vascular excitement, and continued his wonted diet; but when repeated depletions and vegetable or low diet were adopted, great augmentation of the tumour and fatal results soon followed. In three cases which occurred in my own practice, and in which the method I am about to recommend was employed, a marked amendment was the consequence.

46. In order to devise a rational method of treating this formidable lesion we should consider, in the first place, the process adopted by nature to remedy it; and having correctly interpreted this process, we should endeavour to assist

nature in accomplishing it. We have seen that aneurismal dilatation, &c. of arteries, particularly of the aorta (§§ 14, 15.), commences in slow inflammatory action, and that as the coats dilate or rupture, lymph is thrown out, which coagulates the blood, entangling its fibrine and red globules, and thus a fibrinous coagulum, attached to the inner surface of the vessel, is formed, and by its aid the inflamed and otherwise diseased coats of the vessel are strengthened, particularly as the fibrinous layer of coagulum becomes more and more consolidated or organised. Now, what are the circumstances proper to the circulation and state of the constitution calculated to promote this change on the one hand, or to counteract it on the other; for whatever advances it, or assists nature in its completion, will tend to remedy the disease; whilst whatever counteracts it, will lead to fatal results? I shall first consider the measures calculated to counteract the process which nature adopts to remedy the disease.

47. a. I believe that there is no position in pathology more firmly established, since it was insisted upon by JOHN HUNTER, than that whatever greatly lowers the vital energies will impede the formation of coagulable lymph and fibrinous coagula, especially in diseased vessels; and that increased rapidity of the circulation, throbbing of the arteries, abstraction of the fibrine and red globules of the blood, by repeated or large depletions, and the absorption of serous, watery, or unassimilated materials into the current of the circulation, in order to supply the place of the portion of blood abstracted, will, with other effects, inevitably tend to prevent those changes from taking place which we wish to bring about. That large depletions produce increased quickness of the pulse, reaction of the heart, throbbing of the arteries, and all the effects now instanced, must be evident to every thinking and experienced observer; and that these effects are actually those which counteract the changes which nature produces, in order to remedy disease of the circulating system, must be equally manifest. That these results will be still further promoted by undue, or too great abstinence, is no less obvious; and yet, how frequently do we find both inordinate depletion and unreasonable abstinence recommended, in the very teeth of their fatal consequences on numerous occasions, for the cure of aneurisms.

48. b. But what are the means which are calculated to advance the process which nature uniformly adopts in order to restore as nearly as possible the vessel to a healthy state? These may be stated, in a few words, to be whatever restrains or retards the action of the heart, without reducing the vital energies of the frame, and the preservative influence they exert, both on the coats of the vessel, and on the surrounding structures. Conformably with this view, *strict quietude of body and mind*, a light digestible diet, the careful avoidance of spirituous and malt liquors, and the adoption of moderate general or local depletions, only if the state of the circulation unequivocally requires them, are chiefly to be relied upon; and, as far as my own observation, and the careful study of the cases recorded by various writers have enabled me to judge, they are the only means which deserve any share of confidence. Whilst change of air is generally

beneficial, exercise on foot, or on horseback, especially the latter, must be avoided, and the utmost attention should be always directed to the digestive, secreting, and excreting functions.

49. When, in consequence of the energetic action of the heart, or the plethoric state of the circulation, or excessive action of the tumour, we determine on depletion, it ought to be performed in the recumbent posture; and the quantity as well as the manner of abstracting it should be such as to prevent any risk from too great depression, and its consequent reaction, whether of the heart or of the arteries. When the disease is attended with paroxysms of palpitation, depletion will be seldom of any use, and should therefore be cautiously employed in such cases. *Local depletions* may be resorted to when local pains are complained of; but, if the tumour has nearly reached any of the surfaces, they are seldom productive of benefit.

50. *Digitalis* has been generally recommended; it may be of some service when exhibited cautiously, and in moderate doses, but its full effects must be guarded against. The same remarks apply to *colchicum*. The *superacetate of lead*, combined with the acetic acid, and small doses of opium, is preferable to *digitalis*; and any hurtful effect that would arise from it will be prevented by an occasional dose of castor oil. In cases attended with palpitation of the heart, or inordinate pulsation of the tumour, I have prescribed the *sulphate of zinc*, and the sulphate of alumina, generally combined with small doses of *camphor* and *hyoscyamus*, with considerable benefit as palliatives. The acetate of lead may also be exhibited in a similar state of combination.

51. The application of *ice* to the tumour has been advised by continental physicians; but it is often productive of much distress. A lotion, or repeated sponging, and occasionally the continued application of epithems may be employed; and either of those recommended in F. 157. 332. 336. may be adopted. Perfect repose, however, morally and physically, with careful prevention of plethora and sur-action of the heart, is indispensable; other means will be useful, chiefly in as far as they conduce to these states. By endeavouring in this manner to bring about the spontaneous cure of aortal aneurism, it may be supposed that we risk inducing the obliteration of the vessel: but I believe that this is not so likely to occur in the aorta as in smaller arteries; and even were it to occur, the result does not appear so hazardous as the continued increase of the aneurismal tumours; as sufficient evidence is on record of the possibility of a collateral circulation being established.

52. IV. RUPTURE OF ALL THE COATS OF THE AORTA, without aneurismal dilatation of the vessel, is a very rare occurrence, and has been met with only after violent external injuries, such as falls, or leaping from a great height, and from mental excitement, when the vessel has been previously diseased. In the *Ephemerides Physico-Medicæ Naturæ Curiosorum* (*Dec. iii. Ann. ii. Obs. 70.*), a case is recorded, in which it was ruptured by a blow on the hypochondrium. Mr. JAMES has recorded an instance of rupture and instant death in an active seaman, previously in good health, from jumping out of his hammock (*Lond. Med. and Phys. Journ.*, vol. xviii.);

and Mr. ARNOTT has given a similar case, produced by a violent concussion of the body, from falling from a scaffold (*Ibid.*, vol. lviii. p. 19.). The most instructive case, however, of rupture of the aorta without aneurism has been minutely detailed by Mr. ROSE (*Lond. Med. and Phys. Journ.*, vol. lviii. 4to. p. 15.). In this case, as in the others, the coats of the aorta were all ruptured. They were more readily lacerated than usual, and the inner coat had a thickened stertomatous appearance. A case is given by Dr. HUME (*Glasgow Med. Journ.*, vol. iv. p. 148.), in which rupture of the aorta took place in a strong man upon getting into bed, followed by death in a few hours. An aperture, the size of a quill, was found in the vessel about two inches above its bifurcation. No account is given of the state of its coats.

53. V. CONSTRICTION AND OBLITERATION OF THE AORTA have been observed by several pathologists. STÖERCK (*Annales Méd. ii. p. 262.*), MECKEL (*Mémoires de Berlin, 1756*), SANDFORD (*Observat. Anatom. Path. iv. No. 10.*), and Dr. GRAHAM (*Trans. Med. Chir. Soc.*, vol. v. p. 287.), with other recent authors, have recorded cases of extreme constriction of the aorta; whilst M. DESAULT (*Journ. de Chirurg. 1792*), M. BRASDOR (*Recueil Périodique de la Soc. de Méd. à Paris*, t. iii. No. 18.), Dr. A. MONRO (*On Aneurisms of the Abd. Aorta*, p. 5.), Dr. GOODISON (*Dub. Hosp. Rep.*, vol. ii. p. 193.), M. VELLEPEAU (*Revue Méd.*, t. iii. 1825., p. 326.), and M. REYNAUD (*Journ. Hebdom. de Méd.*, t. i. p. 161.), have adduced cases wherein this vessel was entirely obliterated, the circulation having been preserved by the anastomosis and enlargement of the arteries sent off above and below the seat of obliteration.

54. With respect to the origin of this lesion, it may be referred primarily to inflammation of the vessel. But various intermediate changes will necessarily have taken place, from the more immediate effects of inflammation to the complete obliteration of the vessel. It is probable that, in some rare instances, as in large arterial trunks, the transverse rupture of the internal membrane of the vessel, with the consequent effusion of lymph, and formation of fibrinous coagula, may so obstruct its canal as to give rise to its partial or total obliteration, without any aneurismal tumour having formed; and it is not improbable that obliteration or constriction of the canal may have proceeded in other cases, from the advanced stages of the spontaneous cure of aneurism; the deposition of fibrinous coagula, and the subsequent changes which had taken place in them, and the diseased coats of the vessel, having ended in obliteration, and the establishment of a collateral circulation.

CLASSIF. — 2. *Class. Nervous Diseases*; 1. *Order, Comatose Affections (Cullen)*. 4. *Class. Nervous Maladies*; 4. *Order, Affecting the Sensorial Powers (Good)*. 1V. *CLASS, III. ORDER (Author, see Preface)*.

1. **NOSOLOG. DEFIN.** *A loss of consciousness, feeling, and voluntary motion; or in other words, a suspension of the functions of the brain, respiration and circulation being more or less disturbed.*

PATH. DEFIN. *Consists of defective vital energy with hæmorrhage, or derangement of the vascular system of the brain, and their consequences.*

2. **DISTINCTIONS.** There are few diseases which present a greater variety of modes of attack, or which depend upon a greater number of lesions of the organ affected, than that now under consideration. Its sources, modes of manifestation, and morbid relations are numerous, and many of them difficult of investigation. These circumstances have given rise to various attempts at arranging the phenomena of the disease in such a way as to indicate the relations which subsist between the changes within the head, on which it depends, and the mode and progress of attack. Apoplexy has long been described as consisting of certain forms, which have been distinguished by some authors as the *sanguine* and *serous*, with reference to the nature of the effusion; by others, as the *nervous* and *bilious*, according to their idea of the more immediate causes. By several writers it has been, with more justice, divided into *active* or *sthenic*, and *passive* or *asthenic*; or *eutonic* and *atonic*, according to the state of the constitutional or vital powers and respiration, and the degree of vascular action accompanying it. All these arrangements are, however, only partially founded in truth: in many respects they are entirely erroneous. Wherein they are either the one or the other will appear in the sequel. **M. CRUVEILLIER**, one of the most recent and best writers on the disease, confines the term apoplexy to the occurrence of spontaneous hæmorrhage in the brain, and divides it into two species: — 1st, That consisting of a collection of blood in a torn part of the brain, or on its surface from a ruptured vessel; and, 2d, That with sanguineous infiltration into the softened structure — or capillary exudation into, and combined with, its substance. The defects of this arrangement, as well as of this pathology, particularly in regard to practical purposes must be apparent; for it will often be

impossible to ascertain, during life, whether extravasation of blood has actually taken place, or merely great congestion of the vessels, with or without serous effusion; and many cases of true apoplexy occur occasioning death, as well as where complete recovery takes place, without either of the lesions to which he imputes the disease having existed.

3. In the account which I will endeavour to give of the disease, its common form of approach and attack will be described; next, the different modes in which the attack is made, distinguishing the principal forms it assumes; and afterwards will be noticed several important states of the malady, arising from peculiar causes and antecedent affections. When detailing the different varieties and states of the disease, it will be made manifest that the distinctions heretofore offered, although occasionally obtaining, have no uniform or even general relation to the lesions existing within the head; that apoplexy, with the symptoms described as characteristic of *serous* effusion, has been frequently found to proceed from sanguineous extravasation; and that the *sanguineous* has sometimes only presented slight serous effusion: a similar objection being also applicable to all the other distinctions above enumerated.

4. **I. DESCRIPTION.** — i. **OF THE APPROACH, OR PREMONITORY SIGNS, OF APOPLEXY.** The importance of recognising the approach of this disease, must be evident to the practical reader; for judicious measures, employed at this period, will often succeed in preventing an attack, or will render it less severe, even when they fail of averting it altogether. The most common precursory symptoms are, a tendency to sleep at unaccustomed periods; a heavier sleep than usual, particularly if accompanied with profound, laborious, or stertorous breathing, stridor of the teeth; nightmare; succussions of the frame, or cramps; a lethargic feeling and drowsiness even during the waking hours; more rarely, unusual wakefulness; pains in different parts of the head, or general headache or megrim; a sense of weight or fulness in the head, or of pulsation of the arteries; incoherent talking, resembling intoxication; a turgid appearance of the veins of the head, particularly of the forehead; lividity or redness of the countenance; slight or imperfect attacks of epistaxis; loss of recollection; irritability of temper, or unusual serenity or apathy of mind; a disposition to shed tears; suffusion of the conjunctiva; collapsed appearance of the *alæ nasi*; moats floating before the eyes, or dimness of vision (*amaurosis*); scintillations, or bright or shining coruscations before the eyes during darkness; inability to follow the line in reading; double vision, or a sharper sight than usual; difficulty in shutting or opening the eyes; noises in the ears; dulness of hearing; a sensation of an unusual factor; dryness of the nostrils, continued sneezing; frequent yawning; singultus; stammering, or indistinct articulation; the substitution of one word for another, or forgetfulness of words and names; difficulty of swallowing, or fits of coughing upon deglutition; leipothymia, vertigo, or a sensation approaching to faintness; difficulty of writing, or inability to spell the words, or to follow a straight line; torpor, or numbness, or pricking of the extremities; itching, or formation of the surface;

pains of the joints or limbs; a feeling of fatigue upon slight exercise; partial or slight paralytic affections, chiefly of the muscles of the face, or confined to a limb or part of a limb, occasioning drooping of the eyelids, imperfect utterance, slight distortion of the mouth; an unsteady or tremulous gait; tripping upon ascending or descending a stair, or in walking; difficulty in voiding the urine, &c.

5. ii. THE CHARACTERISTIC SYMPTOMS, OR THOSE CONSTITUTING THE ATTACK. After one or more of the foregoing signs, or after the succession of two or more of them, and their continuance for a short or long period, the phenomena which constitute the disease supervene. Sometimes the premonitory signs are so slight, and of so short duration, as to escape notice, the attack being severe and sudden: at other times they are very remarkable, and several of them are grouped together, the attack advancing either gradually and severely, or suddenly, and disappearing rapidly; yet recurring after an indefinite time. The mode of approach and attack sometimes has a close relation to the state of internal lesion; but, occasionally no such relation can be traced, as will be shown and explained hereafter. The premonitory signs, as well as the early part of the attack, generally present more or less either of *augmented* or *diminished* vascular action, particularly about the head, according to the state of the vital powers. The character of the symptoms, therefore, in respect of degree of vascular action and constitutional power, should receive the utmost attention, as being our best guide to a successful treatment.

6. A. In the most *severe* and *sudden* forms of attack,—the *Apoplexia fulminans* of the older authors, and some of the continental writers of the present day; the *fortissima* of Dr. COOKE and others; the *apoplexie foudroyante* of the French,—the patient is struck down instantly, sometimes froths at the mouth, has a livid countenance, complete relaxation and immobility of the voluntary muscles and limbs, and unconscious evacuation of the urine and fæces; and dies very shortly afterwards, either with or without stertor, or rattle of the respiration, with cold, livid extremities, cold perspiration, and sometimes a cadaverous cast of countenance.

7. B. In the more *active* or *sthenic* forms of attack,—the *Apoplexia fortis*; the *entonic* apoplexy of Dr. GOOD; *A. exquisita* of various authors,—the patient is more or less suddenly seized with profound stupor, the eyes being either open or closed; the breathing deep, slow, sonorous, or stertorous; and the pulse slow, full, hard, or strong: sometimes irregular or unequal. In this state of the disease, the above are often the chief symptoms, no signs of paralysis being observed. But frequently the mouth is drawn to one side, the eyes are distorted, and one eyelid immovable, with relaxation, loss of sensation and of motion of a limb, or of one side of the body; the arm of the non-paralysed side being often closely applied either to the chest or to the genital organs. In this latter state of the disease, there is sometimes also some degree of paralysis of the urinary bladder, or of its sphincter, giving rise to ischuria, or enuresis, or a combination of both. The patient generally lies on the paralysed side, which is relaxed, incapable of motion, and insensible to

the application of irritants; whilst the limbs of the opposite side are sometimes subject to spastic contractions.

8. C. In the more gradual seizures, or those of a less complete character,—the *atonic* apoplexy of Dr. GOOD; the *Apoplexia imperfecta*, the *parapoplexia* of various writers,—the patient, after experiencing some of the premonitory symptoms, is seized with alarming vertigo, leipothymia, or feeling of faintness; sickness at stomach and vomiting; disturbance of the senses, particularly of the sense of sight; loss of memory; partial loss of sense, consciousness, speech, and voluntary motion; weak, irregular, and sometimes quick pulse, with more or less of sopor.

9. Besides the foregoing forms of apoplexy,—which differ merely in respect of the state of the constitutional powers, the severity of attack, and the grouping of the symptoms, and not as to the organic lesions which occasion them,—other distinctions offer themselves, which are still more deserving of attention, as generally having a more intimate relation to the changes which are going on within the head, than the degrees of severity of seizure merely. Viewing, therefore, the premonitory symptoms as common to all its varieties, I shall divide the disease according to the form, manner, and complication of the attack, and consider, briefly,—1st, The sudden form of apoplectic seizure, in its simple state, and unassociated with paralysis; 2nd, The gradually increasing, or *in-gravescent* attack; 3rd, These states of seizure complicated with paralysis; and 4th, that form which commences with paralysis, and after an indefinite period passes into complete apoplexy.

10. iii. SIMPLE AND PRIMARY APOPLEXY. A. *Description.* In this variety of the disease the patient falls down deprived of sense, consciousness, and voluntary motion, is like a person in a very deep sleep, with his face much flushed, tumid, and occasionally livid; his breathing slow, deep, and stertorous; his pulse full, natural in frequency, or slower than usual. Sometimes slight convulsions of the limbs, or contractions of the muscles occur, or contractions of the muscles of one side, and relaxation of those of the other. The attack, in rarer instances, is either ushered in or accompanied with general convulsions, passing into complete apoplexy, or profound coma. The patient may continue in this state of profound stupor for several days; or he may recover after some hours, or even minutes, when judicious assistance has been instantly procured.

11. B. This form of the disease *terminates*, 1st, in perfect recovery,—often in the course of a few hours,—but rarely when the attack has continued longer than one or two days. I have, however, seen cases of perfect recovery in comparatively young or robust subjects, after the apoplectic state had been of several days' duration. 2nd, In death, which may take place in the course of a very few hours, or after some days, but most commonly from the first to the fourth day.

12. C. The *appearances* which this class of cases present on dissection may be arranged into—1st, Those which are insufficient to account for the symptoms, or their termination in death; 2nd, Those which proceed from intense injection and congestion of the membranes of the brain, and of the cerebral structures; 3rd, Those which are accompanied with an effusion of serum, or engorgement

of the vessels of the head, or both; and, 4th, Those which are attended by extensive extravasation of blood.

13. 1st. Cases of apoplexy in which *no morbid appearance* could be detected after death, have been recorded by WILLIS, STARK, POWELL, and ABERCROMBIE; and similar cases have occurred to MORGAGNI, TISSOT, QUARIN, OZANANAM, FODERÉ, and HILDENBRAND. It is to this variety of apoplexy that the term *nervous* has been applied by several eminent authors, particularly by KORTUM, ZULIANI, and HILDENBRAND. NICCLAÏ referred it to spasm of the meninges; LÉCAT and WEIKARD to spasm of the nerves and vessels of the brain. BORSIERI termed it *convulsive* apoplexy; and TISSOT and some other authors *hysterical* apoplexy. HILDENBRAND conceives that it is the cause of death in contagious typhus; patients dying after profound coma in this disease, without any effusion or appearance of congestion or compression, but apparently from a sudden collapse of the nervous energy of the brain. Apoplectic seizures, rapidly terminating in death, have been occasionally observed to occur in *epileptics* and maniacs, as recorded by FODERÉ, NACQUART, BELLOC, and GENDRIN, without any manifest lesion of the encephalon. This particular state of the brain seems also, in some instances, to obtain in the course of a few other diseases, and to be occasioned by certain external causes, particularly injuries producing concussion of the brain, lightning, extreme cold, and poisonous substances.

14. A case occurred to me of this description in a man aged about forty, who had complained of vertigo, leipothymia, and loss of recollection, suddenly followed by profound sopor. He had been blooded largely when I saw him. His breathing was not stertorous; his pulse was weak, small, and quick, and his countenance sunk. The brain, on a careful examination, presented no change in colour or consistence, and was even less vascular than usual. The pineal gland was, in my opinion, smaller and softer than natural, and contained scarcely any of the small gritty bodies which are generally found in it. The pituitary gland was not examined, the case having occurred to me a number of years ago, and before my attention had been directed to the nature and functions of this part.

15. 2d. In a large proportion, however, of this class of apoplectic cases, *excessive injection of the vessels of the pia mater, and engorgement of the whole vascular system of the encephalon*, are the chief lesions. The pressure to which the brain has been subjected from this cause, as well as the interrupted state of the circulation, whence the attack most probably proceeded, being sufficient to destroy life in a few minutes, or a very few hours at the furthest. This forms the simplest state of sanguineous apoplexy, and is of comparatively rare occurrence. It constitutes the *coup de sang* of the French, and is observed in those cases of *coup de soleil*, or sun-stroke, which proves rapidly fatal. I have met with it in two cases of this description.

16. 3d. *Serous effusion* is one of the most frequent appearances found in this form of apoplexy; but it seldom occurs alone, being generally accompanied with engorgement of the veins and sinuses of the brain. It is often also observed in the symptomatic and complicated states of apo-

plexy which will come under consideration in the sequel. The very judicious observations which have been made by Dr. ABERCROMBIE and M. CRUVEILLIER, particularly the former, as to the relation which this lesion presents to the apoplectic state, is well deserving of the attention of the pathologist. I perfectly agree with them in considering the distinction proposed between sanguineous and serous apoplexy as not supported by observation; for many of the cases which terminate by serous effusion, exhibit in their early stages all the symptoms usually assigned to sanguineous apoplexy, such as flushed countenance, strong pulse, vigour of constitution, &c.; whilst, on the other hand, many of those accompanied by paleness of the countenance and feebleness of the pulse will be found to be purely sanguineous; even the pre-existence of dropsical effusion, or the leuco-phlegmatic diathesis, or great age, &c., furnish no certain data, although a strong presumption, of the attack being that depending upon the effusion of serum.

17. The serous effusion in those cases in which it constitutes even the chief lesion, cannot be viewed in any other light than in that of a result of pre-existing disturbance of the circulation, depending, as will be more fully alluded to in the sequel, either upon imperfect vital tonicity or action of the vessels, or upon obstructed circulation, especially in the veins and sinuses of the organ, or even upon both. Another circumstance, well deserving of notice, and evincing that the serous effusion is of itself to be viewed as merely a part, and indeed no very important part, of the existing lesions, although the most demonstrable, is the fact also insisted on by Dr. ABERCROMBIE, that the quantity of fluid effused bears no proportion to the degree of the apoplectic symptoms: for we find it in large quantity when the symptoms have been slight; in small quantity when they have been both strongly marked and long continued; and, finally, we find most extensive effusion in the head, where there have been no apoplectic symptoms at all. The inference, therefore, clearly deducible from the most faithfully observed facts, is, that the effusion is not the cause of the apoplectic seizure, but the consequence of that state of circulation on which the disease more immediately depends. Indeed, I am even of opinion that a considerable portion of the effusion takes place either immediately before death, or soon after life is extinct; and that several cases referred to serous effusion have not arisen from this cause, the quantity of serum having evidently not been greater than we have reason to believe naturally exists in the head, as necessary to the regularity of its functions, under the varying states of circulation, and of atmospheric pressure on the surface of the body, from which the unyielding bones of the cranium protect it.

18. 4th, *Extensive extravasation of blood* is a rare occurrence in this form of apoplexy, being most commonly observed in other varieties of the disease. When, however, extravasation is met with, it is either found diffused about the base of the brain, and pressing upon the medulla oblongata in the fourth ventricle, or in both the lateral ventricles, from rupture of some diseased vessel, or from extravasation of blood near to, with laceration of the cerebral structure at, the surface of

the brain. When extravasation of blood is found, the attack has generally been characterised by symptoms closely approaching those of the next variety, viz. an invading and slight attack, rapidly followed by a short interval of sensibility, which is as quickly followed by profound coma and death.

19. iii. THE GRADUALLY INCREASING OR INGRAVESCENT APOPLEXY. — *A. Description.* — In this form of the disease the patient is not at first seized with loss of sense and voluntary motion; or if he be so seized, the attack is momentary, and passes off without the use of any remedy. It more usually commences with a violent and sudden attack of headach, very frequently accompanied with paleness, sickness, and vomiting. Sometimes the patient sinks down from its severity, pale, faint, and exhausted; and experiences a slight convulsion, but recovers from this state in a short time. This invading and slighter attack generally soon abates, or some of the symptoms subside, and others continue in various degrees or differently modified. The pain is generally referred to one side of the head, and the vomiting sometimes returns. Coldness, paleness, and faintness are complained of, with all the other symptoms indicating a serious shock received by a vital organ. The pulse is weak and frequent, the countenance cadaverous and sunk, and the patient feels depressed, but sensible. After this state has endured from an hour, to two, three, or even more, the surface acquires some heat, and the pulse improves in strength. The face now becomes flushed, and the features expanded. The oppression increases rapidly; he answers questions slowly and heavily, and at last sinks into a state of profound stupor or coma. The period which elapses from the invading attack, to the continued and perfect coma, varies from less than an hour to three days. But Dr. ABERCROMBIE, who has illustrated this form of apoplexy in an able manner, has observed an interval of not more than twenty minutes, and has seen it prolonged to a fortnight.

20. *B.* This is the most fatal form of apoplexy, very few recovering from it. On inspection after death, extensive extravasation of blood is always met with. From the whole history of this class of cases, Dr. ABERCROMBIE thinks that they depend upon the rupture of a considerable vessel without any previous derangement of the circulation, the rupture probably arising from disease of the artery at the part which gives way. He conceives that, at the moment when the rupture occurs, a temporary derangement of the functions of the brain takes place, but that this is soon recovered from; and the circulation then goes on without interruption, until a quantity of blood has been extravasated sufficient to produce coma. This may possibly be the case, particularly in those instances where the coma soon follows the first attack. I am more inclined to think that a depressed or deranged state of the vital energy and circulation of the brain, similar to that which occurs in the foregoing variety of the disease, takes place at the commencement of the seizure, and that the extravasation frequently accompanies the reaction, supervening on the oppression which precedes the perfect attack; or, if extravasation have taken place in the first instance, that it is only to a small amount, the state of energy of the cir-

ulation of the organ at the time preventing it from proceeding to any considerable extent, and that it is afterwards renewed in the same situation, or even in a different part, upon the reaction which takes place soon after the shock which the first seizure occasions. Dr. ABERCROMBIE is of opinion, that in some cases the extravasation commences with the early part of the attack, and that it goes on until such a quantity has been accumulated as is sufficient to produce fatal coma; and that in others, after the rupture has taken place, the hæmorrhage is stopped by the formation of a coagulum, and, after a considerable interval, bursts out afresh and is fatal. It is by no means improbable that some cases present the phenomena which this accomplished physician contends for, whilst others may proceed in the manner which I have suggested. A chief reason for my believing that this form of apoplexy frequently originates in the way I have stated, is, that I have met with cases in which the disease was gradual, or consisted of several attacks of either incomplete or complete loss of recollection and voluntary motion, from which the patients had recovered, but had at last been carried off by a more severe seizure; and yet, upon dissection, appearances of recent extravasation merely, or of congestion and engorgement, with or without serous effusion, but without the least extravasation of blood, were the only lesions which existed.

21. The rapidity with which the disease advances, will, of course, depend upon the nature of the lesion, and upon the size of the vessel or vessels from which the hæmorrhage proceeds, and the extent of the extravasation. The situation, also, will have some influence; inasmuch as a small extravasation, if it press upon the medulla oblongata or the annular protuberance, will be more certainly and rapidly fatal than a much larger effusion into the ventricles, or into the substance of the hemispheres.

22. *C.* The Appearances on Dissection, chiefly consist of extensive extravasation of blood, most commonly in some part of the brain in the vicinity of the ventricles, as the corpora striata and thalami optici, or some other situation adjoining those cavities, and which frequently lacerates the cerebral structure, and passes into and fills the ventricles. In some instances the hæmorrhage takes place in a part of the brain nearer to its periphery than its internal surfaces: in such cases the blood ruptures the cerebral substance, and is effused on its surface. In the more suddenly fatal cases, this is observed to have occurred generally towards the base of the brain.

23. In cases of profound coma supervening after a considerable time from the first seizure, the parietes of the cavity formed in the substance of the brain by the effused blood, are softened, discoloured, and broken down, evidently indicating that in these cases softening and disorganisation had either preceded the seizure, or speedily followed the first extravasation, and that a recurrence of the hæmorrhage had produced a lacerated opening, communicating either with the ventricles or the exterior surface of the organ. In a considerable proportion of cases of this form of apoplexy, the arteries are either ossified or otherwise diseased. The veins and sinuses also sometimes present morbid appearances (§ 29.).

24. In rarer instances the extravasation of blood takes place in the *cerebellum*. When the effusion is either in this situation or below it, the symptoms are more severe and rapid in their progress than when it is in the substance of the brain. This remark is also applicable when the blood flows from or into the substance of the annular protuberance, or accumulates around the medulla oblongata and foramen magnum. In some of those latter cases, which are much rarer than the foregoing, the fatal result is rapidly produced. In nearly all the cases of extravasation taking place, either within or near the surface of any part of the cerebral structures, it is extremely difficult, if not entirely impossible, to trace its exact source, or the vessel or vessels whence it has proceeded. It is very probable that the laceration produced by hæmorrhage separates several vessels, and thus a greater number are laid open than are concerned primarily in producing the extravasation. Besides, the softening of the surrounding cerebral structure may destroy additional vessels, and give rise to secondary extravasations of blood, either into the original cavity, thus forming a more recent portion or layer of coagulum, or into the surrounding structure in the state of capillary infiltration.

25. Besides the foregoing sources and seats of extravasation, others have been observed. M. SERRES describes a case in which the hæmorrhage had occurred in the substance of the pons varolii, whence the blood had hurst into the occipital fossa. It may also take place from the superficial vessels, forming the *meningeal apoplexy* of this writer. In cases of this description, the blood generally seems accumulated between the dura mater and arachnoid; but cases have been recorded, in which the blood appeared to have been discharged from the *retiform plexus* of vessels at the base of the brain, and confined beneath the pia mater. The hæmorrhage may also proceed from *ulceration and rupture of a considerable arterial vessel*. Dr. MILLS met with a case in which it was traced to ulceration and rupture of the basilar artery; and MORGAGNI and SERRES have found it proceed from a similar lesion of the internal carotid. MORGAGNI, DE HAEN, and HUFELAND, have traced the extravasation to the vessels of the *choroid plexus*. This is probably the source of the hæmorrhage when it is confined to the ventricles, without laceration of the surrounding substance of the brain. Rupture of one of the *lateral sinuses* has also been observed: a case of this description occurred to Dr. DOUGLAS. (*Edin. Med. Essays and Observ.* vol. vi.)

26. *Small aneurisms* in various parts of the cerebral vessels may have formed, and by their rupture occasion apoplexy. SERRES relates cases in which aneurism occurred in the basilar artery, and in a small artery in the circle of WILLIS. (*Archives Gén. de Méd.* t. x. p. 419.) Similar cases are also recorded by BLANE and HODGSON. Numerous other instances of extravasation from disease of the cerebral vessels have been noticed by MORGAGNI, LIEUTAUD, DE HAEN, BAILLIE, PORTAL, LALLEMAND; and especially by BOUILLAUD (*Mém. de la Soc. Méd. d'Emul.* t. ix.), and Dr. BRIGHT (*Medical Reports*, vol. ii. p. 266, *et seq.*), who have adduced several proofs of this kind of lesion. In a case of apoplexy recorded

by BANG, the extravasation had taken place between the occipital bone and dura mater. Dr. WATTS, of New York, met with a case in which the hæmorrhage had proceeded from the erosion of a vessel in connection with caries of the inner surface of the parietal bone.

27. *Infiltration* of the blood into, with softening of, the cerebral structure, also seems to form one of the lesions which are sometimes met with in this form of apoplexy, although not nearly so frequently as in the seizures which supervene on, and are accompanied with, paralysis, where this state of softening forms the principal lesion; whereas, when it occurs in this variety, it is one of several other changes, or at least a subordinate one.

28. Perhaps the most common causes of hæmorrhage in this form of apoplexy, particularly when occurring in the substance of the brain, are ossification, earthy deposits in various places, and a peculiar friability, of the vessels of the organ. This state of the vessels, as disposing to aneurism and hæmorrhage, has been well illustrated by SCARPA, and is justly insisted upon as being connected with apoplexy by ABERCROMBIE and CRUVEILLIER, and frequently met with in the brains of elderly persons. "There is much reason to believe," Dr. ABERCROMBIE remarks, "that this diseased condition of the arteries of the brain may give rise to a variety of complaints in the head; and that, after going on for a considerable time in this manner, it may at length be fatal by rupture." The remarkable frequency of osseous or cretaceous deposits, &c. in the arteries of the brain in cases of apoplexy, had been noticed by CONTRETIUS and MORGAGNI. There can be no doubt that changes of this description, in connection with alterations of calibre and of vital cohesion taking place in vessels, the coats of which are remarkably thin and fragile even in the healthy state, will readily dispose them to rupture; particularly when influenced by the varying actions of the heart, and the different emotions of the mind, or when congested by derangement of the vital energy bestowed on them by the ganglial system, or by disorder of the veins or sinuses, and interruption to the return of blood through those channels. Indeed, there is every reason to believe that the hæmorrhage may even proceed from the smaller veins, in many of the cases where congestion has been concerned in originating it, and especially when the return of blood from the head has been interrupted so as to produce the disease. It may therefore be inferred, that the laceration of the cerebral structure is occasioned by rupture of either an arterial or venous capillary vessel or vessels, and extravasation of blood; and that, in cases of this description at least, the morbid change commences in the vessels, and not in the cerebral tissue itself, the cerebral structure being only consecutively diseased.

29. Cases have also occurred, in which this species of apoplexy has arisen from disease of the *sinuses*, chiefly thickening, induration, and obstruction or obliteration of their canals. When this is the case, the veins running into the sinuses are generally enlarged, tortuous, engorged, and as if varicose. I have met with cases in which all the symptoms of this disease proceeded from the development of tumours in the central parts of the brain, and similar instances have been recorded by several writers.

30. Besides disease of the *vessels* of the brain, lesions of the *membranes*, as ossific deposits, ossification of the *falx* (MORGAGNI), but particularly derangements of the circulation in them, especially in the *pia mater*, — as evinced by copious extravasation on the surface of the hemispheres, or at the base of the encephalon, — and inordinate injection and congestion, deserve to be enumerated among the sources of this variety of apoplexy; although they are, perhaps, more frequently productive of congestion and serous effusion, and consequently of the most common forms of the preceding species. But there can be no doubt that this form, as well as the foregoing, will also sometimes proceed, although much more rarely, from injection and engorgement of the vessels of the membranes and of the brain itself, without extravasation; and that in other instances the degree of congestion, and the accompanying serous effusion, when occurring without extravasation, are not of themselves sufficient to account for the fatal issue, without imputing something to the vital condition of the encephalon itself.

31. iv. APOPLEXY COMPLICATED WITH, OR TERMINATING IN, PARALYSIS. — *A. Description.* — This form of the disease may take place either suddenly or in the manner of the immediately preceding variety; but more frequently the latter, with the additional phenomenon of paralysis, which may be either coeval with the attack, or supervene as the apoplectic state passes off. In the majority of cases, the patient complains of symptoms referrible to the head, particularly of acute pain in one part of it; and is suddenly or gradually seized with stupor or profound coma, loss of speech and voluntary motion — with perfect apoplexy. The mouth is often distorted, and the patient moves the limbs of one side; whilst one or both limbs of the opposite side are found to be deprived of all motion upon their being pinched or tickled. The patient generally lies on the paralysed side, and one or both the opposite limbs are sometimes contracted or slightly convulsed.

32. In other cases, the seizure is less perfectly apoplectic in its character, varying in the degree of coma and disturbance of the respiration; and, as the seizure declines, the paralytic symptoms become the prominent disease. In some instances of this description, the comatose state is slight or of short duration; but the eyelid, or orbicularis of the eye, of one side is paralysed; or the eyes are distorted, the mouth twisted, and the tongue drawn aside upon its being held out. In the majority of these cases, the speech is either altogether lost or greatly impaired; but the patient appears sensible of his situation, and even attempts to express himself by words or signs: but he is frequently incoherent, unintelligible, and without recollection, even when the power of speech is partially retained. In many of this class of cases, complete hemiplegia exists, or gradually manifests itself as the seizure declines. Sometimes one limb only is affected, which is commonly the arm; although the leg is sometimes the only paralysed part. In rare cases the power of swallowing is lost, owing to paralysis of the muscles of the pharynx and the upper part of the œsophagus.

33. This form of apoplexy presents various modifications in its further progress, which may be arranged under the following heads: —

a. The apoplectic attack may, under judicious treatment, pass off entirely and quickly, and leave no trace of its existence after a short time; the paralytic symptoms, particularly when slight, either disappearing with it, or soon afterwards.

b. The recovery from the apoplectic seizure may be more gradual, taking place only in the course of some days; whilst the paralytic symptoms require several or many months for their removal.

c. The apoplectic seizure may be either quickly or slowly removed; but the paralysis may be permanent, — may continue for years, either until the patient is carried off by a subsequent seizure, or by some other disease.

d. In other cases, the patient experiences a very partial recovery merely, or is subject to several exacerbations; is confined to bed or his room, speechless or paralytic, or the latter only, with his mental faculties either more or less impaired, or but little affected; and at last sinks gradually exhausted, after many weeks, or even months; sometimes having become comatose for a short time before death.

e. The apoplectic seizure may pass off in a shorter or longer time, leaving either hemiplegia, or paralysis of a single limb, or impaired speech and mental faculties; and may recur after a period of indefinite duration, and either carry off the patient, or leave his symptoms greatly aggravated. In this latter case, either another seizure again takes place after a time, or he sinks into the state characterising the immediately preceding modification.

34. *B. The morbid appearances* which this variety of apoplexy, in its different states, presents, are very diversified: — 1st, In some cases, no lesion is detected sufficient to account either for the symptoms or the termination; 2d, In other cases, serous effusion merely to a slight extent, or little beyond what we have reason to suppose usually exists within the cranium, is found, sometimes conjoined with more or less congestion of the vessels; 3d, In some instances, congestion is the most remarkable and only morbid appearance; and, occasionally, this state is connected with disease of the arteries, generally of the kind already described (§ 28.).

35. 4th. *Extravasation of blood* into a defined cavity is amongst the most frequent lesions met with in this form of apoplexy. We have already seen, that, when the hæmorrhage is very considerable, or bursts its way into the ventricles, or to the surface of the brain, the apoplectic seizure is complete; and, owing to the quantity of blood effused, and the pressure thereby occasioned on the whole encephalic mass, the patient is either suddenly carried off before any paralytic symptoms become evident, or rendered comatose, and incapable of sensation and voluntary motion in every limb. In the majority of cases in which extravasation takes place in this form of apoplexy, there is every reason to believe, from its small extent, that it is merely a consequence of the simple apoplectic state occasioned by congestion or interruption to the circulation, — these states of the circulation being followed by the extravasation, on which the paralytic symptoms chiefly depend.

36. 5th. The extravasated blood presents various appearances, according to the period which has elapsed from its effusion; and the surrounding

portion of the brain, and parietes of the cavity formed by the coagulum, likewise undergo changes—in some cases extremely slight, in others very extensive—which generally have an intimate relation to the various states the patient has presented in the progress of the disease. When the cerebral substance surrounding the extravasated blood continues but little changed, coagula of considerable size are gradually and often completely absorbed. About fifteen or twenty days after the attack, the more fluid part of the effused blood disappears, and the coagulum is firm and of a dark brownish colour. At a remote period it assumes more of a firm and fibrous texture, and the dark red or brown tint is lost. At last the coagulum is nearly or altogether absorbed; and a small quantity of fibrinous matter, of a slightly reddish colour, which after a time passes into a loose cellular-looking substance, only remains. These changes generally take place at the end of four or five months; but exceptions not infrequently occur. RIBÉ found blood in the apoplectic cavity after twenty months; MULLIN met with a small coagulum at the end of a year; and SERRÉS has observed firm coagula at the termination of two and three years.

37. The *parietes of the cavity* also experience an important change. They frequently consist of a firm yellowish membrane; and, when the coagulum is altogether absorbed, this membrane forms a more or less complete cyst and well-defined cavity, which is either empty or contains a little very loose cellular substance connecting its opposite sides in all directions; sometimes with yellowish bands of a denser consistence running through it. Dr. ABERCROMBIE has never found the cavity entirely obliterated; while Dr. BRIGHT, M. CRUVELLIER, and some other French pathologists, have seen it in some instances, after a remote period, reduced to a dense nucleus; and, in others, to a linear induration resembling a cicatrix (§ 53.). In some cases the cyst has been found distinctly organised, and with blood-vessels ramified in it.

38. The firm membrane constituting the *apoplectic cyst*, or covering the sides of the cavity, seems to form soon after the extravasation has taken place, and apparently arises from the lymph thrown out upon the torn surface of brain. It may generally be detected as early as a fortnight or three weeks after the attack, or even earlier. At a remote period, when the coagulum is removed, it is either empty, or it contains a serous fluid, usually tinged with blood or the remains of the coagulum. RIBÉ and other French writers suppose that the serous fluid is exhaled from the membrane covering the cavity, and absorbed after dissolving a portion of the coagulum. When blood is extravasated into the ventricles in cases of this description, although extravasation in this situation much more rarely occurs in this than in the preceding form of the disease, there seems no doubt of the possibility of its absorption. In this case, the membrane lining the ventricle, containing the effused blood becomes thickened, and of a yellowish colour. M. RIBÉ records a case of apoplexy, with palsy of the left side, which was completely removed. The patient died of diseased lungs after eighteen months; and the *right* lateral ventricle contained a small quantity of coagulated blood, and its membrane was changed as now de-

scribed. Absorption of the coagulum, with the formation of a cyst similar to those formed in the cerebral structure, also takes place when the blood is effused on the surface of the brain, or in the cellular structure of the arachnoid and pia mater.

39. As the coagulum disappears, the paralytic symptoms in some cases subside; but more frequently the improvement is only partial, and the patient continues paralytic, although the coagulum is either altogether or in a great measure absorbed, and all unusual pressure or interruption to the circulation is removed from the adjoining parts of the brain. It would seem that the fibres of cerebral structure being once ruptured, and not being susceptible of a direct reunion, remain ever afterwards incapable of conveying volition to the paralysed limbs, which are always on the side opposite to the seat of lesion in the encephalon.

40. In some cases of apoplexy complicated with paralysis, the apoplectic symptoms pass away speedily; and the paralysis also disappears, either with the apoplectic attack or very soon afterwards. In these, sufficient time for the absorption of extravasated blood has not elapsed: are we therefore to infer that it has been effused, and recovery taken place notwithstanding? I am more inclined to think that no effusion has occurred in these cases; but that either congestion of vessels in a part of the brain, sufficient to interrupt the functions depending on it, or retardation of the circulation through it, owing to deficient vital energy of the part, occasioning a temporary abolition of its functions, particularly the power of voluntary motion, or both these states, have merely existed. In many cases, one or more coagula, in distinct parts of the brain, or cavities or cysts in older attacks, are found, and generally their number has a relation to the number of seizures. But it occasionally happens that extravasation takes place in two parts of the encephalon, either at the same time or during the same attack; and thus the number of lesions will be greater than of the seizures: and in other cases, particularly in the next form of the disease, the second or even third extravasation takes place in the same situation as the first; forming either an external layer with appearances distinct from the centre coagulum, or a separate portion with the characters of more recently effused blood.

41. 6th. The *substance of the brain* surrounding the extravasated blood often presents important lesions; chiefly consisting of change of consistence and colour. This portion of brain is sometimes very much softened, and is either colourless, or of a yellowish or greenish yellow tint; or presents the usual appearances proceeding from capillary injection or sanguineous infiltration. This change of structure seems to commence from five to ten days after the sanguineous extravasation, and to arise from inflammatory action having taken place in the part surrounding the effused blood. We have already seen that the formation of a membrane around the coagulum, upon the lacerated surface of brain, is necessary to the reparation of the apoplectic effusion; and that the membrane seems formed from lymph thrown out upon this surface. If the local action necessary to the production of

this membrane and to the process of reparation pass the healthy standard, inflammation is the result; occasioning either a considerable effusion of serum or a second hæmorrhage, as already stated, or softening of the surrounding cerebral structure. This consecutive inflammatory action may also give rise to exhalation of serum into the ventricles or into the sub-arachnoid cellular tissue, according to the situation of the primary extravasation; or even, though much more rarely, to a secretion of puriform matter. It sometimes happens, when the consecutive inflammatory action has been slight and of long duration, *induration* of the surrounding cerebral texture takes place, the intellectual faculties having been generally much impaired in these cases; which, however, are much less frequently met with than those of consecutive softening.

42. There is no part of the brain exempt from the lesions described under this form of apoplexy, although they are most frequently observed in the corpora striata, the thalami, and the substance of the hemispheres. They likewise occur, though less frequently, in the cerebellum, annular protuberance, &c. In all these situations the paralytic symptoms affect the side opposite to that in which the lesions of the encephalon are seated. Some exceptions, however, to this have been recorded; but either the various circumstances connected with the cases, in which they have been said to have occurred, have been insufficiently investigated, or they admit of explanation without invalidating the accuracy of the general inference. Of *forty-one* cases in which extravasation of blood was found in the brain on dissection, by M. ROCHOUX, eighteen were in the left side, seventeen in the right, and six in both sides. Of these forty-one, there were twenty-four in the corpora striata; two in the thalami; one in both these situations; and one under the corpus striatum: making altogether twenty-eight cases in the corpora striata and vicinity. Of the remaining cases, five were in the middle of the hemispheres; two in the posterior part of the ventricles; two in the anterior and interior part of the hemisphere; three in the posterior and interior part; and one in the middle lobe. (See art. BRAIN—Alterations in Substance—Hæmorrhage.)

43. V. APOPLEXY, COMMENCING WITH PARALYSIS, WHICH, AFTER AN INDEFINITE PERIOD, TERMINATES IN A COMPLETE APOPLECTIC ATTACK.—*A. Description.*—The commencement of this form of disease is various. The patient often complains of pain, vertigo, and other symptoms referrible to the head; with want of recollection, loss of memory of words, cramps, pains, or with numbness, pricking, tingling, or weakness of a limb or limbs on one side, generally beginning in the hand. The speech is sometimes at first affected, or the mouth and eyes distorted; the limbs being subsequently paralysed. In many instances the local symptoms continue in a state short of paralysis for a considerable time previously to this state being fully developed. In this case, inflammatory action seated in a part of the brain has often existed, although the symptoms have been so obscure as not to have been detected. After a period of indefinite duration, the paralytic symptoms are followed by a complete apoplectic seizure, occasionally preceded or accompanied with spasms or convulsions of the unparalysed limbs;

or the attack supervenes on repeated aggravations, or after a gradual increase and extension of these symptoms. In some cases the patient sinks gradually into a comatose state; from which he may at first be partially roused, and give rational answers, the state of complete loss of sensation and voluntary motion having gradually advanced. From this state the patient seldom or never recovers. In certain cases the apoplectic seizure is more sudden, but is not so profound, or it passes away more quickly than in others. The apoplectic attack having occurred, the patient is either carried off by it, or he recovers after a time the state in which he was previous to it, or he is left by it in a still worse condition: either gradually sinking, and at last dying in a state of exhaustion or coma; or experiencing a recurrence of the apoplexy, which terminates his existence. This forms a variety of M. CRUVEILHIER'S second species of apoplexy. It is often a result of previous acute disease, proceeding from a feeble capillary exudation.

44. As soon as the patient suffers the first complete apoplectic seizure, the *progress* and *termination* of the disease very closely agree with the description given of the immediately preceding form; but the appearances observed on dissection are frequently somewhat different, and are altogether much more diversified.

45. *B. Appearances on Dissection.*—Many of the changes observed after this form of the disease are entirely similar to those described under the foregoing head (§ 41.); whilst others fall under a different article, where they are fully described (see article PARALYSIS). There are some lesions, however, which seem more strictly related to the present variety of complicated apoplexy, than either to the other varieties of the disease on the one hand, or to simple paralysis on the other. The most frequent morbid appearance which I have met with in this form of apoplexy, or seen described in the works of BAYLE, RECAMIER, CAYOL, ROSTAN, RIOUÉ, SERRES, CRUVEILHIER, LALLEMAND, BUILLAUD, ABERCROMBIE, and GENDRIN, who have paid great attention to its pathology, consists of softening, with a reddish tint, of a portion of the brain. In cases which I have examined, the softening was accompanied with *infiltration* of blood into the cerebral structure. In some cases the softening and infiltration increased from the circumference to the centre, whilst in others the change from the healthy state to this took place abruptly; the diseased part presenting the appearance of a cavity containing a softened and reddish pulaceous mass, which could be removed without evincing any connection with the surrounding brain. In some instances the softened part is of a yellowish green tint, and the surrounding portion of brain more vascular than natural. The parts most commonly affected with this lesion are nearly those which are most frequently the seat of hæmorrhage; the chief difference being, that the grey substance of the hemispheres is oftener the seat of the former than of the latter.

46. As to the *origin* of this particular form of softening of the cerebral structure, I must refer the reader to what I have adduced respecting it in the article on the *Alterations in the Substance of the Brain*. As, however, the origin of this

species of softening has a very intimate relation to the treatment of this class of cases, it becomes a matter of importance to trace its origin. The French pathologists, with very few exceptions, ascribe it to inflammation of the cerebral structure. There can be no doubt that it sometimes proceeds from this source. But as soon as the inflammatory action has given rise to this change, the vessels no longer enjoy their requisite tone—their vitality has evidently become exhausted, and they allow the red particles of blood to escape from them, and to be infiltrated into the cerebral structure; as we observe sanguineous infiltrations into the parenchymatous structures, to occur in scurvy or in purpura hæmorrhagica. When the softening arises from this cause, the paralytic and apoplectic seizure more frequently is met with in patients not far beyond the middle age, and whose constitutions are not much injured; and the attack is more commonly preceded by acute or febrile symptoms, than when it proceeds from the cause about to be adduced.

47. Dr. ABERCROMBIE considers that it also depends upon disease of the arteries, chiefly ossification, thickening, contraction, or separation of their inner coat, occasioning a failure of the circulation, and gangrene of the part of the brain which is supplied by the diseased vessels, as is observed to take place in the toes of aged persons. This may possibly occur; but still we have no satisfactory proof that it does so. This far I may concede,—that the disease proceeds from a change of a state of the capillaries of the part, and of the cerebral structure in which they ramify, otherwise we should not observe infiltration of blood, and great softening of structure; but which of the two is the primary lesion is very difficult to determine. Most probably, both are dependent upon the state of that part of the ganglial system which supplies the encephalon, particularly its blood-vessels.

48. The other appearances with which this lesion is associated in this form of the disease, consist of the morbid states of the arteries of the brain already noticed; of aneurisms (BLANE records a case which arose from rupture of aneurism of the internal carotid); congestion of the vessels, veins, and sinuses; more rarely extravasations of blood in some one of the situations and states already noticed, or the remains or marks of antecedent hæmorrhage; empty cysts from which coagula have been absorbed; portions of the brain in various degrees of induration; purulent collections in different forms; encysted and other tumours of various descriptions; a large proportion of the lesions described in the articles on the *Alterations in the substance of the BRAIN*; thickening, injection, or ossifications of the membranes; and, occasionally, accumulations of serum in the sub-arachnoid cellular tissue, and in the ventricles. The further exposition of this form of the disease, especially in relation to the *paralytic* symptoms, falls more appropriately under the head of PARALYSIS, where they are fully discussed.*

* I may subjoin the following classification of apoplexies, according to a different principle to that adopted above. It is based upon the chief pathological states from which the attack proceeds, and approaches nearer the arrangements adopted by the German pathologists, particularly HARLESS (*Der Speciellen Nosologie*, &c. p. 131. Cobl. 1824.), than that usually followed by our own writers. In some respects it may be preferable to that which has

49. VI. OF THE PHENOMENA OF THE DISEASE WHICH HAVE NO PARTICULAR DEPENDENCE UPON ITS SEPARATE FORMS.—A. There are *certain symptoms* occasionally met with in all the states of apoplexy, to which I shall briefly refer. The *pulse* is frequently full, strong and slow, or of natural frequency, particularly in the *first, third, and occasionally in the fourth varieties* into which I have divided the disease. In other cases, especially in those which are extreme, and particularly in the *second and fourth varieties*, it is often small, feeble, and unequal or irregular. The *respiration*, both as to strength and frequency, generally presents similar characters with the pulse: when the latter is slow and strong, the former is deep, slow, and stertorous; and when the pulse is weak and frequent, respiration is quick, less laboured, and much less sonorous. *Deep sighs* are occasionally observed in all the forms of the disease. The *state of the pupils* is very various: sometimes they contract and dilate independently of the influence of light; but in the *first and third varieties* they are generally dilated; and they are often contracted, or one is contracted and the other dilated, in the *second, third, and fourth varieties*. Contraction of the pupils has been remarked as a not infrequent attendant on the worst forms of apoplexy, and particularly on those characterised by a tendency to spastic action, by ARETÆUS, and recently by CHEYNE, COOKE, and various other pathologists. The *features* are usually large, bloated, relaxed, and flushed; but they are sometimes pale, and even collapsed, particularly in the *ingravescent and consecutive forms* of the malady. The *facial and urinary evacuations* sometimes take place involuntarily, in all the varieties of the disease.

50. The *muscles* most frequently paralysed, either antecedently, consecutively, or at the same time, with apoplexy, are those of the superior and inferior extremities, particularly those of the superior; next those of the tongue and face; and lastly, the muscles of respiration. In general, the power of feeling is more or less deficient, as well as of voluntary motion of the affected

been now fully described, particularly as I have placed those forms of the disease which depend upon the nervous or vital energy of the encephalon in a more prominent point of view, than they can hold in a classification framed according to the symptoms and mode of seizure, in connection with the internal lesions.

I. SANGUINEOUS APOPLEXY, — with extravasation of blood in some part within the cranium.

II. CONGESTIVE AND SEROUS APOPLEXY, — from obstructed return of blood from the head, and frequently from the metastasis of gout, rheumatism, or eruptive diseases.

III. ASTHENIC APOPLEXY, — *Nervous Apoplexy of Authors*, — from depression, exhaustion, or abolition, of the vital influence bestowed on the encephalic organs, and occasionally giving rise to extravasation of blood, or of serum, and to congestion of the cerebral vessels.

A. From *intoxication*. B. From *narcotic poisons*, and *acphitic gases*. C. From a *stroke of lightning*. D. From the *influence of great or continued cold*. E. From *exhaustion of the mental and bodily powers*, and from *convulsive affections*. F. From *violent mental emotions*.

IV. APOPLEXY FROM PRE-EXISTING CHRONIC LESIONS WITHIN THE CRANIUM, — from tumours, inflammations, abscesses, &c. &c.

V. TRAUMATIC APOPLEXY, — from external injuries, *Convulsion*, or shock of the vital powers of the organ; — *pressure* from depression of bone or extravasation of blood.

VI. COMPLICATED APOPLEXY, — supervening at the invasion, or advanced stages of febrile diseases of an adynamic or asthenic type.

limb or side; but sometimes voluntary motion is lost, whilst sensation remains. There are also very rare cases recorded, where the feeling only was lost, and sensation has been observed paralysed on one side, and motion on the other. These phenomena will be more particularly considered and explained in the article on PARALYSIS. As the patient convalesces, sensation returns in the paralysed limb before the power of voluntary motion; and generally the lower extremity recovers its functions before the upper, unless disease of the spinal chord, producing more or less of paraplegia, coexist with, or is consequent upon, the apoplectic disease, — an occurrence which is sometimes met with.

51. *B. The duration of the apoplectic state is extremely various.* The attack may terminate fatally in a few minutes, particularly the *first* variety; or it may pass away in as short a time, and the patient recover, especially in *this* and the *third* form of the disease. Dr. COOKE thinks that death seldom or never occurs in less time than one or two hours, in genuine apoplexy; and I believe, as respects those apoplexies which consist of cerebral hæmorrhage, this is generally the case; but when large hæmorrhage takes place into the ventricles, and about the base of the brain, death is very quickly produced. An attack often, however, continues for a much longer time, generally from several hours to as many days. If no remission of the symptoms, be observed after twenty-four hours, the disease generally terminates unfavourably. The progressive or ingravescent variety sometimes continues for several days; the apoplectic state becoming more and more profound; and at last usually ending fatally.

52. *C. The termination of apoplexy* has already been noticed, when describing the different forms of the disease. I may, however, remark generally that the attack may end as now stated, or it may go off completely, leaving no further ill effects than a tendency to recur upon the action of the remote causes. This favourable termination, however, is entirely owing to the nature of the causes; a larger proportion of cases either terminates in, or is accompanied with, paralysis. When the speech and mental faculties are affected in a marked manner from a first attack, they return but slowly; the memory, the strength of mind, and force of character, are more or less impaired; the patient becomes weak, puerile, easily excited, and timid; and a disposition to a subsequent attack is produced, which either carries him off, or weakens still further his mental and motive powers, until perfect imbecility of mind and body is occasioned. Sometimes, after repeated attacks, with marked injury of the mental faculties, a considerable diminution of the volume of the cerebral convolutions is observed upon dissection, — they no longer fill the cranial vault; but the space is occupied by a greater or less quantity of serum infiltrated in the sub-arachnoid cellular tissue, and not only on the exterior surface of the convolutions, but also between their anfractuosités. In some cases this change is more remarkably developed in certain convolutions than in others, or in those of one lobe or hemisphere than in the rest.

53. *D. The changes* which the seat of hæmorrhage undergoes have already been described at

length (§§ 37—40.). The most remote changes which have been observed in the ruptured part of the brain, from which the coagulum has been absorbed, are, in some cases, a complete cyst, either empty or enclosing a little reddish serum, or a loose cellular substance; in a few instances, a firm nucleus, seemingly consisting of the fibrous remains of the coagulum, and in others, according to CRUVEILLIER, merely a linear induration from the cicatrisation of the lacerated cerebral structure. In whatever form the remains of the coagulum and laceration may present themselves, at periods remote from the seizure which these lesions occasioned, no direct union of the divided fibres of the brain is observed to have taken place. Even when an *apparent* union of the divided cerebral structure is noticed, it will be found to have been brought about indirectly, and through the medium of the cellular or fibrous substance left after the absorption of the coagulum; the cavity having gradually closed, owing to the atrophy of the ruptured fibres, and the hypertrophy of those surrounding them from having had to perform additional offices.

54. *E. Of the supposed relations subsisting between the seat of hæmorrhage, or lesion of the brain, and the symptoms accompanying and following the attack.* — M. CRUVEILLIER states that those parts of the brain most subject to hæmorrhage, or laceration from the external injuries occasioning counter-stroke of the cranium, most commonly present extravasation of blood in apoplexy. This seems to some extent correct, as far as relates to corresponding frequency; but there are parts of the encephalon, occasionally the seat of apoplectic hæmorrhage, which are seldom or never so affected from this species of external injury.

55. *a.* It has been supposed by MM. SERRES, FOVILLE, and PINEL-GRANDCHAMP, that lesions of the *corpora striata* are followed by paralysis of the lower extremities, and those of the *thalami* by palsy of the upper. This inference is, however, neither supported by anatomy, nor borne out by facts: a mere coincidence of internal lesion with external signs cannot always warrant the inference that the disordered function has its origin in the part diseased, especially when we are ignorant of the offices of such part. The upper and lower extremities are most frequently paralysed from apoplexy; and the *corpora striata* and *thalami* are the parts in which the apoplectic hæmorrhage most frequently occurs. Hence the coincidence of these lesions of structure and functions must be frequent. But these parts of the brain are sometimes diseased without the correspondent affection of the limbs contended for; whilst, on the other hand, the extremities are often paralysed without any lesion of those parts.

56. *b.* The disciples of GALL consider the *anterior lobes* of the brain as presiding over the organ of speech, and as the seat of the memory of words, &c., and that therefore lesions of this part affect this organ, as well as this particular state of recollection. M. BOUILLAUD has supported this opinion by the history of several cases; and M. CRUVEILLIER has controverted it, by adducing the details of others (*Nouv. Biblioth. Méd.* 1826). Several other French pathologists have also espoused opposite sides, and adduced cases supporting their views. The inference deducible

from the facts already accumulated is, that a coincidence of lesion of these functions, and of these parts of the brain, is sometimes observed; but the relation between them is neither so uniform nor so precise as to warrant the opinion that there exists any necessary dependence of these particular functions upon the parts of the brain to which they have been ascribed. Without reference, however, to the part of the brain on which the memory of words depends, it has been remarked by M. *ITARD*, that aged persons struck by apoplexy frequently lose the recollection of them in the following order:—First, want of recollection of proper names, next of substantives, afterwards of verbs and adjectives; which last are often the only words which can be recollected.

57. *c.* It was contended by MM. *DELAÏE*, *FOVILLE*, and *PINEL-GRANDCHAMP* (*Nouv. Journ. de Méd.* 1821), that disturbance of intelligence depends upon lesion of the *grey substance* of the brain, whilst disorder of locomotion proceeds from change of the white or *medullary structure*. But this doctrine seems no better founded than the preceding, being open to the same objections which have been urged against them. Lesion of the *cineritious substance* is, perhaps, more frequently accompanied with spasms and convulsions at the commencement of the attack, than when it is seated in the medullary structure.

58. *d.* *The cerebellum.*—*MORGAGNI* has recorded that *VALSALVA* once stated to him, that a case of apoplexy to which he was called was seated in the *cerebellum*. Dissection verified the *diagnosis*; but he does not mention the symptoms on which *VALSALVA* founded his judgment. M. *SERRES*, adopting the doctrine of *GALL*, says, that erections or seminal emissions, in men, and discharges, sometimes of a sanguineous appearance, from the female organs, are the distinguishing signs of apoplexy of the cerebellum. M. *CRUVEILHIER* states that he has seen apoplexy of this part, but that these symptoms were not present. Some cases have certainly occurred to countenance the opinion of *SERRES*, and others to overthrow it. It seems more probable that the effusion in the cerebellum affects the *medulla oblongata*, and occasions a partial asphyxia and stasis of the blood, from the influence of this part upon the respiratory class of nerves, and thus induces a state favourable to erection. *CRUVEILHIER* states that he failed to produce this symptom by irritating the cerebellum of dogs. I may, moreover, add, that the symptoms contended for by *SERRES*, and the followers of *GALL*, as distinctive of cerebellic apoplexy, have occurred in cases wherein the cerebellum has been found sound on dissection.

59. Apoplexy of the *cerebellum* occasions, *cæteris paribus*, a more serious lesion of the functions of circulation and respiration, and is more dangerous than apoplexy of the cerebrum. The symptoms are evinced on the side opposite to the seat of lesion, in this as in other apoplexies. The opinions that the cerebellum is the regulator of all the voluntary movements, and the source of all sensibility, according to certain Continental physiologists, particularly MM. *FLOURENS*, *FODERA*, *FOVILLE*, and *PINEL-GRANDCHAMP*, have not been confirmed by the history of apoplexy seated in it. The hypothesis of *ROLANDO*, pro-

fessor at Turin, that the cerebellum performs a function analogous to the Voltaic pile, in generating a fluid or principle requisite to the functions of voluntary muscular action; and that it transmits this fluid, under the influence of the brain, and through the channel of the spinal chord and nerves to the muscles; seems much more accordant with comparative physiology, and the pathology of the nervous system.

60. *e.* *The annular protuberance*—the point of junction of the spinal chord, brain, and cerebellum—the centre of the cerebro-spinal system, is sometimes the seat of apoplexy, notwithstanding its density. When the extravasation of blood in this part is to any considerable extent, immediate and complete paralysis of the trunk, and of both the superior and inferior extremities, is produced, with the most profound lesion of respiration, quickly followed by death. When the effusion is to a small extent, and in one side of the protuberance, the paralysis which results seems on the opposite side of the body, as may, indeed, be inferred from anatomy. The extravasation must be to a small extent, to admit of recovery. Sometimes the effused blood is observed to have been disposed in layers between the lamina of white matter entering into the structure of the protuberance. The reparation of the apoplectic lesion of this part takes place in a similar manner to that which I have already described (§ 37—40.). It would seem that the smallest division of the fibres of this part is followed by permanent affection of feeling and motion.

61. Connected with this subject, M. *FLOURENS* concludes, from his experiments and observations, that the cerebral lobes, the cerebellum, and the tubercula quadrigemina, may lose a considerable but limited portion of their substance, without losing the exercise of their functions; and they may re-acquire them after being totally deprived of them: that the spinal marrow and the medulla oblongata are the only parts which directly affect the same side of the body with that in which they themselves are affected; whilst the tubercula quadrigemina, the cerebral lobes, and the cerebellum, alone produce these effects upon the opposite sides to that in which they are diseased,—the former acting in a direct course, the latter in a cross direction. These inferences, however, want confirmation in several particulars.

62. II. *DIAGNOSIS.*—Apoplexy is, in general, readily recognised: but it may occur in such a way and under circumstances which will render its diagnosis a matter of difficulty. Thus we may be called to a patient, of whom nothing is known, with the following symptoms:—Coma, laborious or stertorous breathing, relaxation or rigidity of the limbs, complete loss of consciousness; he may or may not have had convulsions, or a blow upon the head; there may be hemiplegia or not. In this case, is the patient in a state of dead drunkenness, asphyxied, poisoned by narcotics, or affected with the profound coma consequent upon epileptic or hysteric convulsions? Is it concussion of the brain; the advanced effects of organic disease within the head—as of cysts, abscess, or of inflammation terminating in effusion; or fever, either at its commencement or close, with apoplectic symptoms? It is true that these states differ but little from apoplexy; the difference consisting chiefly in grade, unless

hæmorrhage has taken place when paralysis generally manifests itself. But it should be at the same time recollected, that there is sometimes hæmorrhage without local palsy, and even palsy without sanguineous extravasation. The diagnosis of such cases is very important; but without information of the circumstances connected with the history of the case, its difficulty is extremely great. I once treated a case of adynamic fever, originating in infection, and commencing with sudden loss of sense and voluntary motion, as a case of apoplexy, and gave an opinion accordingly. The history of the case, and its subsequent course, showed the error. When paralysis is present, the nature of the case is then manifest, although the particular cause of the palsy may be a matter of doubt. We should, therefore, inquire after this symptom by observing the attitude and motions of the patient, by pinching the extremities, tickling the soles of the feet, &c. The existence, also, of stertorous, laborious, or snoring respiration, will confirm the diagnosis.

63. *a.* It should be kept in mind that, whilst the comatose state consequent on *epilepsy* or *hysteria* may closely resemble apoplexy, the convulsive stages of these diseases may give rise to the true apoplectic state. But, in the usual consecutive coma of epilepsy there is no stertorous breathing, and the limbs are not so relaxed as in apoplexy. The *coma*, which supervenes to inflammation of the membranes of the brain, is chiefly to be distinguished from apoplexy by the antecedent symptoms, and by the loss of sense and cerebral function being greater than the loss of motion; independently of the association of paralysis, so frequently characterising the apoplectic seizure.

64. *b.* The symptoms consequent upon *injuries of the head*, whether simple concussion, or compression from depressed bone, or extravasation of blood, are in all respects identical with certain of the varieties of apoplexy described above, and are not to be distinguished from them, but in respect of the exciting cause. A similar remark is applicable to cysts, tubercles, and other tumours slowly developed in the encephalon, which sometimes produce no very marked external sign of disease, until apoplexy, and still more frequently hemiplegia, suddenly take place. In such cases there is no actual difference in the proximate cause of the abolition of function, but only in the compressing body whereby abolition of function is occasioned.

65. *c.* In cases of loss of sense and voluntary motion from the action of *narcotic poisons*, or breathing *deleterious gases*, there is also little actual difference from several of the apoplectic states described above (§ 10.), excepting that the functions of the lungs have, in the case of breathing deleterious gases, been primarily affected; for the chief lesion is to be referred to the state of *nervous energy* and *vascular action* in the brain, its circulation being retarded, and its vessels congested with dark blood. Indeed, in many such cases, the true apoplectic condition, either with or without hemiplegia, is produced; although, in the majority, the state of profound but simple coma is the result.

66. *d.* In *asphyxia* the lesion of function commences in the lungs, the pulse being either diminished in strength or entirely abolished; whilst

in apoplexy the lesion is in the head, and the pulse is generally fuller and stronger than natural; but the exceptions to this state of pulse are numerous. In *syncope*, the marked diminution, or almost entire absence, of the pulse, paleness of the countenance, and the very gentle or scarcely apparent respiration, are sufficient to distinguish it from apoplexy, even in its weakest forms; excepting at the commencement of, or early in, the apoplectic attack, when the states of vital energy of the brain, in both affections, are not materially different.

67. *e.* Complete *intoxication* may readily be mistaken for apoplexy; and, in some cases, may terminate in this disease. This state of intoxication is evidently attended with congestion of the vessels of the encephalon. The smell of the breath, and the appearance and smell of the matters thrown up by the retching that frequently accompanies intoxication, will readily distinguish this state. The greater frequency, also, of the pulse, and absence generally of stertorous breathing, in drunkenness, will also assist the diagnosis. But these symptoms are occasionally observed in apoplexy; and, on the other hand, the pulse may be slow or natural, and the breathing stertorous in the former: but this is very rare, particularly slowness of the pulse.

68. *f.* In *concussion* of the brain, the state of its circulation, and the influence of that portion of the ganglial system which supplies it, are as remarkably depressed as in the weakest form of apoplexy,—in concussion from the shock received, in apoplexy from internal causes; in many cases no difference existing. In some instances, however, even of this form of apoplexy, the respiration is much more laborious, the countenance somewhat more tumid or distorted, and the pulse fuller and more developed than in concussion. In the stronger states of apoplexy there can be no risk of mistake, the characteristic symptoms of each being very different.

69. III. PROGNOSIS.—An attack of apoplexy is always dangerous:—1st, It may be fatal immediately; 2d, It may also be fatal within two or three days, and previous to reaction having commenced; and, 3d, It may occasion death during reaction:—*a.* by a recurrence of the attack; *b.* by inflammatory softening and infiltration of the cerebral tissue surrounding the extravasated blood; *c.* by the exhalation of serum; *d.* by inflammatory action of the membranes of the brain and subjacent cellular tissue, and of the membrane lining the ventricles. Even in more favourable circumstances, it leaves behind it debility of feeling, motion, and of the mental faculties; and a first attack is generally followed by a second or even a third.

70. *A.* The *unfavourable* symptoms are frequency or intermittence of the pulse; continuance of the symptoms for twenty-four hours, or for little more than half of this time in the *strong* apoplexy, after a judicious treatment; very profound coma, and obtuseness of the senses; involuntary discharges of the urine and fæces; contraction of the pupils, or contraction of one or both pupils accompanied with spastic actions of muscles; very laborious stertorous breathing, particularly if attended with foam about the mouth, and a weak pulse; cold and profuse sweats; the occurrence of convulsions the association of

hemiplegic symptoms with the apoplectic, and complete loss of vision. Frequent yawning or continued somnolency indicate effusion, or increasing effusion. QUAIN observes very justly, that when the patient frequently applies the hand to a determinate part of the head, or when delirium supervenes, or if partial perspirations occur early in the attack without benefit, the result is generally fatal. Complete hemiplegia, without coma, but with integrity of the mental faculties, and perfect motion and sensation of the non-affected side, is less dangerous than a more partial paralysis, with stupor or coma. When one pupil is contracted and the other dilated, the existence of unequal pressure may be inferred. It has generally been stated that complete loss of feeling and motion, accompanied with coma or stupor, is extremely dangerous. CRUVEILHIER remarks that he has seen recovery in such a case. I have seen it in three cases, one of which was seen by Dr. HOOPER.

71. Delirium is an unfavourable complication; and indicates either the escape of blood from the seat of extravasation upon the membranes which it irritates, or the occurrence of inflammation of the cerebral structure or meninges. Acceleration of the respiration, and vomiting supervening spontaneously, unless from matters occasioning the attack, are very dangerous symptoms. A similar remark is applicable to loquacity, or complete loss of speech, particularly when attended with a frequent pulse.

72. When the disease occurs in the course of insanity, or in epileptics, or after previous attacks, or after palsy, an unfavourable result may be generally anticipated; a nearly similar conclusion may be drawn if it seize aged persons, and broken constitutions, upon the disappearance of gout from the extremities. In the majority of cases of apoplexy proceeding from efficient causes originating in the brain, a perfect recovery is not to be expected. On this, M. PORTAL has insisted strongly; and although it is just as a general rule, many exceptions will present themselves. If the pulse sink, or intermit, or become remarkably quick; and coldness of the extremities, or cold clammy sweats come on; or the power of respiration be greatly diminished; inevitable or fast approaching dissolution may be predicted.

73. B. The favourable signs of the disease are, a moderate attack; a decline of the symptoms after treatment, and particularly if a warm, general, and gentle perspiration take place; the occurrence of discharges of blood from the nose, hæmorrhoidal vessels, or uterus; and a free state of the bowels, with consciousness of all the evacuations. The accession of the menses, of the piles, or of ptyalism, have been justly viewed as the most favourable signs by HIPPOCRATES, SCHADT, DOLÆUS, and many subsequent writers. GOAVARTS considers hæmorrhage from any part, particularly epistaxis, ptyalism, a copious and general perspiration, with free alvine and urinary discharges, the most favourable signs. The accession of fever has been considered favourable by HIPPOCRATES and PORTAL; but many experienced authors do not agree with them. I believe that, although some may recover from this state, it indicates the accession of inflammatory action of the portion of brain or membranes adjoining the seat of hæmorrhage; which will be dangerous in

respect of the extent to which it may proceed, and the effects it may produce on the part, particularly in causing a renewal of the hæmorrhage. In all cases, the practitioner, even under favourable appearances, should give a cautious prognosis until the tenth day; the eighth being that on which an unfavourable change is apt to occur, and the extravasation to be renewed.

74. IV. CAUSES. — The causes of apoplexy, both predisposing and exciting, have generally a direct or indirect influence upon the state of the vital energy and circulation of the brain. The manner, however, in which causes may individually influence either the vital condition or circulation varies extremely; and the action of several of them is even peculiar. Those causes, which in some cases are merely predisposing, may in others be exciting; and changes previously induced in the organisation of the brain, or in the state of its vessels, even from causes which lead to other maladies, may, either directly or indirectly, occasion apoplexy.

75. i. The predisposing causes of apoplexy. — This disease occurs most frequently in persons of the male sex, owing to their habits, and greater exposure to the exciting causes; and in the far advanced stages of life. The majority of authors state the period intervening between forty and seventy as that in which it is most common; but it is not infrequent at both earlier and later epochs, particularly the latter. M. ROCNOUX found, in 63 cases attended with extravasation of blood, that 2 were between 20 and 30 years of age, 8 from 30 to 40, 7 from 40 to 50, 10 from 50 to 60, 23 from 60 to 70, 12 from 70 to 80, and 1 from 80 to 90 years. I have met with the true hæmorrhagic apoplexy at the early age of eighteen. The hereditary tendency of the disease, as shown in several instances by FORESTUS, WEPFER, PORTAL, BLANE, FRANK, and others, cannot be doubted.

76. The form and habit of body may also predispose to the attack; but, I believe, much less frequently than is usually supposed. A large head, short neck, full chest, sanguine and plethoric constitution, and corpulency, are generally considered signs of disposition to it; but the state of the heart's action, and of the circulation through its cavities, with a plethoric state of the vascular system, has a more marked influence, as will appear in the sequel. In the 63 cases which have been minutely analysed by M. ROCNOUX, only 10 were fat and plethoric persons, 23 were thin, and 30 were of the ordinary habit of body. He therefore maintains that there is no external appearance of habit and temperament whereby the disposition to apoplexy is indicated.

77. Long and intense thought; disappointments; depressed and anxious states of mind; the habitual indulgence of the temper, passions, and appetites; the irritable and sanguine temperaments; sedentary and luxurious living; too great sexual indulgence, particularly when accompanied with full living; habits of intoxication, or the too free or constant use of wine and malt liquors; laborious employments, especially when they require the stooping posture; the suppression of accustomed hæmorrhages, discharges, or habitual diseases, particularly those which are accompanied with evacuations; and the neglect of vascular depletion after their suppression; th

influence of other diseases, particularly those of the heart, liver, lungs, kidneys, and digestive organs; a gouty diathesis; extremes of temperature, particularly when conjoined with moisture; sudden vicissitudes of temperature; frequent indulgence in sleep after a full meal; the use of neckcloths worn too closely around the neck; sleeping with too low a pillow, particularly after a meal; and lying too long in bed; are among the most common predisposing causes.

78. ALBERTI and SEIZ have insisted on the greater frequency of this disease amongst the *studious* than in other classes. FRANK says that the greater proportion of his apoplectic patients had been previously subject to hæmorrhoids. The use of *tobacco*, particularly in the form of snuff, has also been considered to favour the occurrence of apoplexy. As to the influence of *weather and seasons*, it may be stated, that MORGAGNI and LANCISI observed this disease most frequently in hot weather suddenly following cold and rainy seasons. KAISER says that he met with the greatest number of cases in the months of October and November; and HIPPOCRATES, GALEN, FORESTUS, KELLIE, and others, have noticed the influence of cold in producing it. I believe that very *cold weather*, or cold conjoined with moisture, favours its occurrence in very old subjects; and that very hot and moist seasons occasion it in robust and plethoric persons. The influence of hot weather in its production has been insisted on by MORGAGNI and CHEYNE. The FRANKS found apoplexy most prevalent at Petersburg and Wilna during the height of summer (J. FRANK, *Prax. Med. Univ. Præcep.* t. ii. p. 308.).

79. Apoplexy seems to be as frequent in the *poorest* as in the *richest* classes; but in the former it is more commonly attended with paralysis, and oftener assumes an asthenic or *weak* character, the attack chiefly proceeding from frequent exposures to the vicissitudes of season and temperature, from severe and long-protracted exertion, and a less nutritious diet. In the latter it more generally assumes the *strong* or active form, arising most frequently from ease, luxury, and various indulgences.

80. It will be observed that nearly all these causes act by habitually favouring determination of blood to the head, or by impeding its return, and by diminishing the vital energy of the brain at the same time that they favour a plethoric state of its capillary vessels. These derangements of vital manifestation and of circulation, when frequently produced, will occasion further changes, and sometimes will, upon the occurrence even of the slightest exciting causes, terminate in those lesions which constitute the disease itself.

81. ii. *The exciting causes* frequently act in a similar manner to the foregoing; but generally in a more sudden manner and intense degree. These are, immoderate perturbations of mind, as consternation, terror, fear, despondency, anger, disappointments, anxiety, distress of mind from losses, sorrow, violent chagrin, great joy, immoderate fits of laughter, and all painful, depressing, or exciting mental emotions and exertions. Numerous illustrations of the immediate influence of the above passions in producing the disease are to be found in the writings of ARETÆUS, FORESTUS, ZULIANI, PORTAI, BOICHER, CHEYNE, COOKE, ABERCROMBIE, &c.

82. *Intemperance* in eating and drinking is amongst the most common exciting causes of the disease; and numerous instances of its immediate ill effects are adduced by the above writers, and by BONET, MORGAGNI, MEAD, FOTHERGILL, and others. Oppletion and distension of the stomach prevent the descent of the diaphragm, impede the dilatation of the cavities of the heart, obstruct the circulation through the lungs and the return of blood from the head, whilst the vital energy is abstracted from the brain, and determined to the digestive organs, in order to dispose of the load by which they are oppressed. Owing to this procession of phenomena the vessels of the encephalon are engorged at a time when their vital energies are diminished; while the rapid influx of fluid matters into the circulation as the process of digestion advances, tends to heighten the vascular fulness and disposition to effusion. Besides, habitual intemperance of this description generates a plethoric state of the system, with congestions of internal viscera. Spirituous liquors are seldom productive of apoplexy until after a continued addiction to them, unless they are taken in excessive quantities; and perhaps the habit of drinking much malt liquors or wine is still more frequently a cause of the disease, than indulging in spirits, which, when they occasion apoplexy, act more upon the vital endowments of the brain, than in causing extravasation of blood; the chief changes produced by them, being serous effusion with injection of the vessels. Sir A. CARLISLE has adduced a case of apoplexy, arising from drinking an immense quantity of gin. Upon dissection, the odour of the spirits was detected in the serum effused in the ventricles of the brain.

83. Connected with the use of spirituous or fermented liquors, I may here allude to the influence of the class of *narcotics*, particularly opium, stramonium, hyoseyamum, tobacco, &c., the excessive use of which sometimes occasions all the symptoms of congestive apoplexy, and even extravasation. Of all the narcotics, the different species of monkshood most readily occasion apoplexy, when taken by mistake. I was consulted in the case of a young man who had incautiously chewed some seeds of this plant; he was shortly afterwards seized with a sense of numbness of the face, soon followed by complete apoplexy, as described under the third variety of the disease, from which he recovered with great difficulty, and with palsy of one side, with which he continued to be affected.

84. Nearly allied to the operation of narcotics is that of the fumes of charcoal, and various *mephitic gases*, which, whilst they diminish, or altogether arrest the changes affected by respiration on the blood, thus occasioning asphyxia, and earn without stertorous breathing, sometimes produce all the symptoms of complete apoplexy, owing to their effects upon the vital endowment of, and circulation in, the brain. In respect of the *modus operandi* of narcotics and deleterious gases on the system, somewhat different opinions have been entertained by CULLEN, GOODWIN, CURRIE, ORFILA, BRODIE, and others who have investigated the subject. There can, however, be no doubt that they act chiefly upon the ganglial system, particularly on that part which actuates the brain, when they produce apoplexy, destroying the influence of this system

on the vessels of the encephalon, and thereby retarding the circulation in, and favouring congestion of, its capillaries, and interrupting the functions of the organ.

85. Violent straining in lifting heavy weights, or *muscular exertions*; straining at stool; the venereal act, particularly under unfavourable circumstances, or too frequently repeated; the metastasis of other diseases, especially of gout and rheumatism; whatever impedes the return of blood from the head, as a dependent posture of the head, or holding it long in an averted position, or looking backwards without turning the body, particularly when the neck is short; sleeping upon too full a meal, especially with a neckcloth or other ligatures around the neck; violent fits of coughing or sneezing; pregnancy and child-birth; exertion of body, with an anxious mind; stumbling; the use of the warm bath; and the sudden exposure to heat or cold; are among the most frequent exciting causes of apoplexy.

86. The effect of the *sun's rays* in producing what is commonly called *coup de soleil*, is well known. Many of the seizures thus occasioned amount to complete apoplexy, in some one of its forms, particularly the first and third. But other conditions of *heat* will also sometimes occasion an attack, as heat combined with moisture, and the exhalations from a number of persons crowded together in ill-ventilated apartments. The influence of crowded rooms and assemblies in causing apoplexy is well known, and in occasioning headache, and sense of fulness in the vessels of the encephalon, even in persons not predisposed to an apoplectic attack.

87. *Cold* also, particularly when applied suddenly to the surface of the body and lungs, excites the disease in aged persons, whose vital energies are already greatly impaired. The vessels of the brain in this class of subjects are weak, fragile, and liable to rupture, or to permit a portion of their serous contents to escape. Besides, cold depresses still lower the vital powers of the frame, and tends to retard the circulation, whilst it drives the blood from the surfaces into the large viscera, and particularly into the encephalon, which, from its unyielding case and exemption from atmospheric pressure externally, is more obnoxious to congestion, retarded or interrupted circulation, and compression from vascular fulness, than any other organ; occasioning lethargy in the robust or young, and apoplexy in the old or predisposed. Cases illustrative of apoplexy produced by long exposure to great cold, particularly when the disposition to sleep which it induces is yielded to; by the incautious use of the cold bath, and of ice applied to the head; and by the practice in Russia and Poland, of using a snow bath after the warm bath; have been recorded by WEPFER, WALTHER, PENADA, MACARD, BRANDIS, KELLIE, PORTAL, and FRANK. Of about fifty perfect cases of the disease, the *causes* were analysed by Dr. CHEYNE, and ranked as follows:—1st, Drunkenness and habitual indulgence in exciting liquors; 2d, The form of the body; 3d, Temperament, sanguine, sanguineo-choleric, choleric; 4th, Gluttony; 5th, Indulgence; 6th, Mental anxiety; 7th, Fits of passion; 8th, External heat; 9th, The use of tobacco. (*On Apoplexy and Lethargy*, p. 149.)

88. iii. *Modus operandi of the above causes.*— If we endeavour to trace the relation subsisting between these causes, and what we know of their uniform effects, either upon the brain or on other parts of the body, we shall find that they tend first to excite, and afterwards to exhaust, the vital energy, and to distend the capillaries of the part. Now, as the brain is enclosed in an unyielding case, it must follow that, when the capillaries are excessively distended, the veins, which are the most yielding, will be proportionately compressed, whilst the force of the circulation in the arteries will tend to perpetuate this distension, and consequently the compression of the veins. Thus the circulation will be retarded; the portion of the ganglial system supplying the brain be likewise, to a certain extent, benumbed by the increased pressure to which it is subjected, and the functions of the organ abolished, even without extravasation having occurred. Upon dissection after death, the blood, which had distended excessively the capillaries, will be found to have passed into the veins, giving the appearances of venous congestion merely, as is uniformly observed in other parts of the frame, which have been the seat of congestion, without inflammation, — venous congestion, at least to any considerable extent, being incompatible with the physical condition of the encephalon during the life of the patient, unless it be occasioned by impeded return of blood through the sinuses and large veins, although congestion of its capillaries undoubtedly frequently exists.

89. When *hæmorrhage* takes place, the effused fluid will occasion more or less pressure, according to its extent; but from the condition of the encephalon, the pressure will almost equally affect all parts of it; the blood being thereby prevented, to a certain extent, from returning by the veins, whilst the capillaries and arteries will be unnaturally distended. This state, however, will pass off after death; and venous congestion only, with extravasation, present itself. When, however, the extravasation is large, the pressure will prevent both the veins and the capillaries from receiving their due proportion of blood; whilst the ganglial system of the encephalon will be analogously, or injuriously, affected. But this topic will be pursued hereafter.

90. iv. *Consecutive and complicated Apoplexy.*— An attack of apoplexy may be caused by other diseases, in various stages and states of their progress. It may occur after the pre-existing disease has disappeared, and in consequence of its disappearance, as in the case of suppressed hæmorrhages, particularly epistaxis and hæmorrhoids; or suppressed evacuations and eruptions, as those from the uterus, bowels, &c.; or it may supervene in such a way as will lead us to infer that its occurrence has been the cause of the disappearance of the pre-existing malady, as in cases of misplaced or metastatic gout, rheumatism, &c.; or it may likewise appear in the course of other diseases which it cannot thus displace, and assume the character of a most serious or fatal complication. The importance of these morbid relations of apoplexy requires for them a more particular notice than they have generally obtained.

91. A. *Consecutive.*— The supervention of apoplexy after suppressed hæmorrhages, evacuations,

and eruptions, has been satisfactorily noticed by many writers; and seems to proceed from unusual fulness of the vascular system, owing to the suppression, and the accidental co-operation of causes which determine the blood to the head, and favour its extravasation. Besides the suppressed evacuations, noticed above (§ 90.) as being influential in causing an attack, I may mention the sudden healing up of chronic ulcers; the arrest of habitual perspiration from the feet; unusual continence; and suppression of the lochia or of leucorrhœa. It is not infrequently observed after suppressed otorrhœa; and from inflammation of the ear having extended to the membranes and substance of the brain, and produced abscess. I have met with several cases of this description in which the apoplectic state was complete, and attended with hemiplegia. Numerous instances are also recorded by LALLEMAND, GENDRIN, ITARD, and other writers. (See BRAIN—Abscess in.)

92. *B. Metastatic.*—The occurrence of the disease, from *misplaced or metastatic gout*, has been noticed by MORGAGNI, WEICKARD, MUSGRAVE, JUNCKEN, TODE, HAGENDORN, CONRADI, and CHEYNE. The last-named author thinks that the symptoms differ, when occurring from this cause, from those which constitute true apoplexy. I believe, however, that they differ in no respect, in general, from those which characterise congestive apoplexy; and that, as hæmorrhage within the head does not commonly constitute the attack of apoplexy from this cause, hemiplegia or paralytic symptoms seldom accompany it.*

93. Nearly similar seizures to the foregoing will occur from attacks, or metastasis, of *rheumatism* to the membranes of the brain. The apoplectic symptoms are, however, seldom so fully developed as in other cases, a comatose state being the more usual result. On dissections of fatal cases of this description, MORGAGNI, HOFFMANN, PLENCIZ, RANOE, WEICKARD, and STOLL, found the membranes injected, thickened, and with serum^m interposed. Very nearly similar symptoms and appearances within the head result from *erysipelas* extending to the membranes of the encephalon. Here, as well as in the rheumatic disease of the same structures, the apoplectic state is not so strongly marked as in its more idiopathic forms; and paralysis rarely occurs, excepting in the advanced progress of the cerebral disease.

94. *C. Complications.*—Apoplexy occasionally supervenes in the course of many diseases, even at the commencement of some of them, and becomes *associated* with them.—*a.* It is sometimes an attendant upon the *colâ stage*, or the period of

invasion, *in fevers*, particularly those which proceed from concentrated marsh effluvia, and from the infection of animal miasms. The epidemic prevalence of apoplexy, noticed by BAGLIVI, LANCISI, MORGAGNI, FORMEY, and STOLL, may be explained by a reference to this connection; although the observations of the FRANKS and CHEYNE, which are conclusive of the great frequency of the disease in hot and moist seasons, seem to countenance the opinion of these authors. When apoplectic seizures usher in fevers, whether paludal or infectious, the attack is seldom accompanied or followed by paralysis. In a case, however, of perfectly formed apoplexy ushering in a case of endemic fever of a warm climate, which occurred in my practice, paralysis supervened upon the seizure. An attack of true apoplexy may also occur in the stages of depression and collapse of adynamic and typhoid fevers, particularly in the former stage: in the latter, coma is generally present, but it very rarely amounts to the true apoplectic state; and when it does, hemiplegia generally attends it.

95. *b.* The occurrence of apoplexy after *epileptic convulsions*, the convulsions and eclampsia of the puerperal state, and, more rarely, during the hysteric fit, is well known. It may even take place during the pains of labour, without previous convulsion, and in the latter months of pregnancy. In these cases the attack offers nothing to distinguish it from the first, second, or third varieties described above. It is a not infrequent termination of *inflammation* of the brain, or of its membranes. Indeed, there seems every reason to suppose that acute inflammation of that part of the cerebral structure in which hæmorrhage takes place, not infrequently precedes the extravasation. It also occasionally supervenes upon *mania*, and the various states of *insanity*, particularly in its fourth or last-noticed form (§ 43.). It also occasionally arises from interrupted circulation through the *lungs*,—a fact well demonstrated by BONET, BANG, HUXHAM, J. FRANK, and CHEYNE. Its occurrence during the advanced stages of both acute and chronic diseases of the *air-passages* and *lungs*, particularly those characterised by violent attacks of cough, has also been observed by myself, most frequently in hooping-cough, bronchitis, asthma, and emphysema of the lungs.

96. *c.* The connection which sometimes subsists between apoplexy and *organic disease of the heart*, especially hypertrophy of the left ventricle, has been remarked by VALSALVA, MORGAGNI, LIEUTAUD, TESTA, PORTAL, CHEYNE, RICHERAND, BERTIN, and HOPE; and has been viewed by them in the light of cause and effect, the apoplectic seizure arising from the cardiac disease. CORVISART and ROCHOUX, physicians of large experience, have thrown doubts upon the nature of this connection; have likewise denied the frequency of its occurrence; and have viewed these diseases as sometimes consecutive in their origin, although co-existent in their advanced state, but without the relation of cause and effect: thus considering the occurrence of apoplexy or paralysis in the advanced stages of disease of the heart as entirely an accidental coincidence. But, as I have contended many years ago, in the London Medical Repository, when such a complication of morbid states is frequent, prominent, and observes the same

* Some years since I was called to a medical friend in Westminster, who, after complaining of symptoms of indigestion, was suddenly seized with complete apoplexy, with stertorous breathing, but with no signs of paralysis, for which the usual means were promptly and decidedly employed. On the following day a complete attack of gout in both feet took place, with disappearance of the cerebral disease. Warmth to the feet, and aperients, were prescribed; but from his eagerness to rid himself of the pain, and to visit his patients, he took, contrary to the advice given him, a large dose of colchicum. A few minutes afterwards the gout left his feet, and seized his stomach; whence it was with difficulty recalled to the extremities. This was the first time he had ever been seized with gout, and the first part it attacked was the brain, in as complete a form of apoplexy as can be conceived. Metastasis of gout to the head may also occasion inflammation of the brain, with coma, or lethargy.

succession, a more intimate connection than mere sequence or coincidence ought not to be entirely rejected, particularly when admitting of a rational explanation. The frequency of apoplexy or paralysis, and the general presence of the latter when the former occurs in the advanced progress of cardiac disease, especially lesions of the orifices, and hypertrophy of the left side of the heart, have led me to believe that more than mere coincidence actually exists. It is, however, by no means improbable that the disposition to organic change throughout the whole vascular system, sometimes associated with disease of the heart, may so far exist in the delicate vessels of the brain, as to favour the occurrence of hæmorrhage from them when the action or impulse of the heart is increased by disease or the influence of passion or emotion; or when the return of blood from the head is impeded by congestion, or interrupted circulation through the lungs or right side of the heart.

97. *d.* The association of apoplexy and hepatic disorder has been noticed by STOLL, BALDINGER, MOLL, CHEYNE, and others. The circumstance of icteric patients frequently being cut off by apoplexy marks the connection. I have met with several cases in which both apoplexy and paralysis have supervened to, and become complicated with, hepatitis, both acute and chronic, particularly the latter. The liver is seldom diseased without disordering the functions of the brain; and I believe that accumulations of vitiated bile in the gall-bladder and hepatic ducts, independently of any actual disease of the liver, will predispose to the apoplectic seizure. I am the more confirmed in these opinions by having observed disease of the biliary apparatus in a very large proportion of those who had died of apoplexy or paralysis; and, in many of those who have recovered, the active use of purgatives had produced morbid evacuations, containing a large quantity of blackish green, greenish, or yellowish brown bile, before much amendment had taken place. It may, however, be conceded that serious disturbance of the brain equally induces disorder of the liver; and that the latter may have been occasioned by the former. But this merely proves the frequency and intimacy of the association. It should also be kept in recollection that the apoplectic seizure generally masks the hepatic affection; the practitioner should, therefore, examine the region of the liver, where, as well as at the epigastrium, fulness, and, in some cases, the existence of tenderness may be detected; and, as the consciousness of the patient returns, the hepatic disorder will occasionally become more manifest. This complication is so important and frequent, that it ought always to be looked for in practice; for many of the causes which occasion hepatic disorder also give rise to cerebral disease: and the production of either the one or the other singly, often favours the appearance of the other subsequently. I have no doubt, however, that an inflamed or actively congested state of the substance of the liver has a very marked effect in exciting that state of the capillary circulation of the brain on which the apoplectic seizure has been shown to depend (§ 88.).

98. *e.* The influence of gastric disorder in producing apoplexy, not merely as evinced by intoxication, a surfeit, &c., but also by some one or more of the several ailments which charac-

terise impeded or otherwise disordered function of the stomach and intestines, has been noticed by SCIENCK, SCHROEDER, WEICKARD, MEZLER, FOTHERGILL, SCHÆFFER, THILENIUS, HUFELAND, LOUYER-VILLERMAÏ, and CHOMEL; and more strongly insisted on by BROUSSAIS and his followers. Although the general dependence of the latter on the former has been too absolutely contended for by BROUSSAIS, the occasional connection cannot be doubted. Indeed, in several of those cases wherein the association with hepatic disorder is observed, gastric and intestinal disturbance is also evinced. But however complicated, whether with either gastric or hepatic disorders only, or with both conjoined, apoplexy is, perhaps, as often the concurrent result of the same causes that produced these disorders, as a disease springing from and dependent upon them. The fact ought not to be overlooked, that the vital manifestations of the stomach, liver, and brain, although different, are yet actuated by the same system of nerves—the ganglial; and that, notwithstanding the individual parts of this system seem to perform modified offices, yet the healthy condition of the one is necessary to the perfect functions of the rest; and, consequently, a morbid state of one considerable portion of the series will necessarily, sooner or later, be followed by derangement throughout,—causes which operate upon one part of the circle, thus having their effects extended to other parts remote from the seat of primary impression. It should not, however, be overlooked that a large number of instances of gastric affection, retching, &c., accompanying the apoplectic seizure, proceeds from the sympathetic effect produced upon the stomach by the severe injury or shock sustained by the brain.

99. *f.* The occurrence of apoplexy, either after, or during attacks of *colica pictorum*, has been noticed by HAGENDORN and CHEYNE. Although palsy is the common consequence and state of complication, yet apoplexy, with or without paralysis, particularly the former, is sometimes met with. An instance occurred to me some time since of a patient having died of apoplexy during an attack of this disease. The *constipated* state of the bowels to which persons affected with cerebral disease are liable, when neglected, or not readily yielding to medicine, will sometimes favour the occurrence of the apoplectic attack.

100. *g.* The association of apoplexy with disease of the kidneys has been noticed by several writers, particularly BONET, LITRE, MORGAGNI, and BRIGHT. The occurrence of apoplexy, particularly serous apoplexy, after suppression of urine, is not uncommon. By some writers, however, the suppression has been imputed to pre-existing disease of the brain. But this is a supposition merely: for, in the great majority of cases, the kidneys and ureters offer evidence of having been the parts primarily affected. The experience of BONET and MORGAGNI, and of numerous later writers, fully support this conclusion. Besides, the cerebral nervous system can only indirectly influence the urinary secretion. That apoplexy, coma, or lethargy, should occur when the urinary secretion is suppressed, and the vascular system overloaded, may be readily imagined. The occurrence of the disease, as a consequence of organic change in the secreting structure of the kidneys, whereby their functions are more or less ob-

tructed, has been illustrated by the cases recorded by Dr. BUGHN.

101. *h.* The sudden or more gradual supervention of apoplexy after the slow development of many of the *organic changes* which are described in the article on the *Pathology of the Brain*,—in some cases even when little cerebral disorder had previously been complained of; in others when more violent and even paralytic symptoms had occurred, has already been noticed (§§ 45—48.), and has also received due attention in the article on *PALSY*.

102. *V. THE PATHOLOGICAL STATES CONSTITUTING APOPLEXY* have been in part comprised in the observations offered on the principal kinds of apoplectic seizure, and on the *modus operandi* of the remote causes (§ 88.). There can be no doubt that much misapprehension has existed on this subject, and consequently that the treatment adopted has been frequently either nugatory or injurious. The opinion that the disease depends upon compression solely, has been too generally adopted, without considering the relation in which such compression, granting its existence, stands in to the causes which occasioned it, and the symptoms it produces. The idea that compression is indispensable to the existence of the disease has thus been empirically assumed, and acted upon in practice. A careful consideration, however, of the morbid appearances on dissection, in relation to the symptoms, and to analogous changes and their phenomena, have led me to infer that compression of the brain never can take place; that *pressure* exists in the great majority of cases, but even that it is not indispensable to the apoplectic state; and that, although *retarded* circulation, whether caused by pressure or by any other state, seems very frequently to obtain, it does not constitute the only morbid condition of the brain in apoplexy,—or, in other words, that apoplexy is not merely a disease of the vessels of the brain, although these vessels are either consecutively or coetaneously affected. It should not, however, be overlooked, that even those who argue for compression being the cause, do not thereby imply, as their opponents would make it appear, that the tissue of the brain is actually compressible, but contend for the effects which pressure undoubtedly produces upon living and sensible parts. Therefore, although the brain is not compressible, it does not follow that it may not be affected by *pressure*, even independently of the obvious effects which pressure must produce on its vessels and the circulation through them.

103. Before entering further on this subject, it will be necessary to premise, that the circulation of the brain, like that of other important organs, is chiefly under the dominion of that portion of the ganglial system of nerves which is ramified on its blood-vessels, and is distributed otherwise to the organ itself; and that an exhausted or morbidly depressed state of the influence those nerves exert on the circulation and manifestations of the brain, with the consequent effect this state has upon the capillaries particularly in dilating or congesting them, and disposing to their rupture, is the principal cause of, and often constitutes, the apoplectic seizure,—whether this influence emanate from their chief centres, or from the local sources provided for the peculiar offices of the organ, as the pineal and pituitary glands.

104. From this it may be inferred, that the proximate cause of a large proportion of the cases of apoplexy, not omitting even those which are attended with retarded circulation and hæmorrhage, is here imputed primarily to the condition of that part of the ganglial system which supplies the blood-vessels of the brain and the brain itself. That this actually is the case, is shown by the nature and mode of operation of the remote causes of the disease; by the frequent affection of the functions of the brain previous to an attack; by the nature of the principal part of the phenomena accompanying the attack; by the disorders observed subsequently, when partial recovery takes place; by the tendency to relapse; and by the morbid appearances which present themselves on the dissection of fatal cases.

105. It is obvious, that the appearances in these cases are merely ultimate lesions, as in all fatal cases of *organic disease*, and some of them even post mortem changes; and yet, although the most advanced in the procession of morbid phenomena, they are often of themselves obviously insufficient to occasion death. Leaving out of question those cases which are unattended with extravasation, the venous congestions, even admitting their existence, or the serous effusion, found in the other cases, are seldom such as to account of themselves for the event: inasmuch as they are frequently observed to an equal, or even greater, extent in cases where neither apoplectic nor comatose symptoms had preceded death; and are, as I have already shown (§ 88.), the result of the accumulation in the veins, after death, of the blood which had distended the arterial capillaries during life, and thus had been instrumental in abolishing the cerebral functions.

106. The circumstance of the morbid changes being insufficient to account for the result, had induced various writers, particularly KORTUM, ZULIANI, SCHELLER, SCHÆFFER, and HUFFLAND, to consider apoplexy frequently to proceed from the state of the nervous power, which they considered defective; and led WEICKARD to contend that it seldom depends upon compression. Dr. ABERCROMBIE, evidently influenced by the above considerations, refers the disease to *interrupted* circulation in the vessels of the brain, owing to pressure from the effused blood, or to other causes. It is extremely probable that a *retarded*, if not an interrupted, state of the circulation very generally obtains; and that, partly in consequence, the sensific and motific powers are not generated. This, however, is only a matter of inference; for we have no evidence that complete interruption of the circulation of an organ or part can exist for any time, and its functions be so rapidly restored, as is sometimes observed in apoplectic seizures, or without gangrenous disorganisation being sometimes the result; and even if we admit this state of the circulation, we must still refer it to some antecedent and more general morbid condition.

107. That a congested state of the vessels and retarded circulation of the brain should, however, exist, owing to the diminished, or exhausted, or suppressed state of that influence which undoubtedly actuates the vessels, may readily be conceded; but that, even in the brain, the effusion of a small portion of blood should occasion pressure sufficient to *interrupt* the circulation through it, requires

further proof. It seems more probable, and consonant with facts observed in other parts of the body, that, in cases where the extent of effusion or external injury warrant the admission of pressure, this state gives rise to the apoplectic seizure, as much from the effects it produces upon the ganglial apparatus of the encephalon as from interrupted circulation through its vessels.

108. THE PATHOLOGICAL CONDITION OF THE BRAIN, therefore, in apoplexies, may be stated to be as follows:—*a.* That the tissue of the brain is not sensibly compressible; but, being lodged in an unyielding case, it may be injuriously affected by pressure, chiefly by displacing the contents of its blood-vessels, altering the healthy relative proportion of their contents in each of the series of vessels, and impeding the circulation through a part or the whole of the organ: and that pressure exerted in one part, whether from distended vessels, extravasated blood, or the development of tumours, when reaching a certain pitch, will almost equally affect the whole of the organ, particularly when the pressure is great: the yielding nature of the cerebral structure, as well as the unyielding case in which it is placed, must necessarily give rise to this result.

109. *b.* The various states of vascular impulse and action, impeding circulation in the veins and sinuses of the brain, and distension of its capillaries, whether arising from the influence of the organic nerves on the blood-vessels, or from morbidly increased action, or from obstruction in the large veins, the lungs, or the right side of the heart, will, either individually or in partial conjunction, occasion the above effects, owing chiefly to the unyielding walls of the encephalon.

110. *c.* Owing also to this physical condition of the brain, the pressure of the atmosphere which influences the venous circulation of all other parts of the body, cannot modify in a direct or sensible manner that of the brain: and hence the cranial cavity must always contain nearly the same quantity of blood during life, the differences which occur being chiefly those of rapidity of circulation, and of relative proportion in each part of the series of vessels; an increased quantity in the capillaries thus causing a proportionate diminution in the veins. Owing likewise to this condition, the forcible injection and distension of one set of vessels will necessarily diminish the capacity of, and obstruct the circulation through, the other; and that part of the series which is nearest to the propelling power—the first to receive the impulse of the heart, and the nearest capable of being much distended by it—will, from relative situation, overcome the distension, and diminish the capacity of that beyond it. Thus the arterial capillaries of the brain will be the first distended from increased action of the heart and large arteries, and, by their distension, will soon overcome that of the veins, if it had previously existed; and hence by compressing them, impede the circulation through them.

111. The frequent *inflammatory character* of apoplexy, or the common occurrence of *reaction*, will be readily accounted for from what has now been stated; for whether the attack commences with dilatation or increased action of the arterial capillaries, or with exhaustion or deficiency of their vital power, or with retardation of the circulation through the veins and venous capillaries, the result will gene-

rally be augmented action of the arteries going to the brain, extending itself in some measure to the heart, and this state will continue until the abolition of the cerebral functions shall have impaired or altogether destroyed, the heart's action.

112. *d.* Upon tracing the relation subsisting between the various causes of the disease, the symptoms and the appearances on dissection—upon remarking, as far as my own observation has gone, the frequency of change in the pineal and pituitary glands of apoplectic patients, I am induced to infer that functional lesion, or organic change, often commences in that portion of the ganglial system which supplies the encephalon and its blood-vessels; and that, owing to exhaustion of its influence, the capillaries lose their vital tone, have their circulating functions impaired, become more or less dilated, and are disposed to rupture.

113. *e.* When apoplexy proceeds from causes of an obviously *exciting nature*, or from *sur-action* of the heart and arteries, it seldom occurs until a certain degree of exhaustion of the vital tone of the capillaries has taken place, whereby they become dilated and congested, so as either to press the encephalon against its unyielding case, and, owing to the pressure, impede the return of blood by the veins (§§ 109, 110.), or to give rise to extravasation, which, when considerable, has a similar effect; injection of the arteries of the brain and its membranes resulting equally from both, owing to the obstructed circulation through the veins.

114. *f.* Where pressure unequivocally exists, it may also benumb or suppress the vital influence of that part of the ganglial system which supplies the encephalon, thereby heightening the effect produced both on the organ itself and on its circulation.

115. *g.* There are cases of apoplexy that present the phenomena, which have given rise to the appellation of *weak apoplexy*, and which occur from *depressing causes*, operating upon exhausted states of the encephalon and frame generally. These causes directly suppress or abolish the vital influence of the organic or ganglial nerves of the brain, and consequently the cerebral functions, without producing further change of its vascular system, than retarded circulation in so slight a degree, as not to amount to great distension and compression, and without occasioning extravasation of blood, although extravasation often does supervene to this state, giving rise to pressure and its consequences, so as to heighten or prolong the primary lesion, and to occasion paralysis.

116. *h.* In cases proceeding from *depressing causes*, acting on a plethoric habit of body, the effect is also more or less directly produced on the organic nerves of the brain, whereby the capillaries lose their tone, are congested and dilated, or ultimately ruptured, and the return of blood by the veins retarded, whilst the smaller arteries and capillaries are more and more engorged by the impetus of the blood in the large arteries, the pressure thereby occasioned suppressing the cerebral functions as in the other cases.

117. *i.* When the disease proceeds primarily from *impeded return* of the blood from the head, the congestion only commences in the veins; but, as the action of the heart and arteries con-

tinues, the capillaries are soon afterwards injected and dilated; and, in proportion as they enlarge from the distending power to which they are more immediately subject, the veins are compressed, owing to the physical condition of the brain, more or less emptied, and admit of the greater dilatation of the capillaries, some one or more of which may be even ruptured from the increased action and distension.

118. *k.* In cases accompanied with *hæmorrhage*, and consequent laceration of the cerebral structure, the deprivation of function may be as much an effect of suppression of the vital influence of the organ, owing to the shock produced by the injury, as of pressure upon the veins, and consequent injection of the arterial capillaries. In cases of this description, the state described above (§ 112. *d.*) may exist, and be followed by *hæmorrhage* and laceration of the part in which it occurs, producing the abolition of the cerebral function, great vital depression, sickness, and other signs of dangerous injury sustained by a vital organ. The pressure occasioned by the *hæmorrhage* will be followed by obstructed circulation, and, under favourable circumstances, by increased action of the arteries and heart to overcome it.

119. *l.* In apoplexy presenting on dissection *congestion* and serous effusion, these states may be often considered rather in the light of *post mortem* changes than the pathological states which had existed previously to death; it may even be presumed that the distension and congestion of the capillaries, chiefly the arterial capillaries of the organ, had overpowered its functions; and that, as in other parts, when the injection of the blood into them no longer is continued, and the distending cause has ceased to exist, they have gradually discharged their contents into the veins, which now had space given them for dilatation, owing to the emptying of the capillaries; and thus the blood has passed into the veins soon after death.

120. *m.* *Hæmorrhage* in the brain may result from the following states: — *a.* Exhausted vital energy of the ganglial organic nerves supplying the vessels and organ favouring their distension and rupture: *β.* Diseased state of the coats of the vessels themselves: *γ.* Organic change of the cerebral structure, extending to, or influencing the state of, the vessels ramified in it: *δ.* Increased impetus of blood from augmented action of the heart and larger arteries, combined with either of the other states: *ε.* Impeded return of the blood from the head, similarly associated.

121. *n.* The vital energy of the organ, resulting chiefly from the mutual influence of the ganglial and vascular systems, may be so far affected as to occasion the attack with all the organic changes observed in fatal cases; and sometimes in such a manner as to constitute the disease, even without these changes having taken place; although they are most frequently produced, thereby heightening the primary lesion.

122. *o.* As corollaries from the foregoing, I infer that apoplexy often originates in exhausted or suppressed influence of the ganglial apparatus of the encephalon, with a congested state of its arterial capillaries, or impaired condition of their circulating functions, and still more frequently in extravasation of blood, either or all of which changes must necessarily exist to the extent of

suppressing the functions of the organ; and that, as apoplexy does not uniformly depend upon the same pathological state of the nervous influence and circulation of the brain, particularly in respect of the kind or degree of vital depression and vascular reaction, a due regard ought therefore to be had to the nature of the change in each case, as far as it may be ascertained, and a treatment strictly appropriated to it adopted.

123. VI. TREATMENT.—The treatment of apoplexy has long furnished subjects for discussion, not only as respects the more subordinate means of cure, but also as regards the most energetic measures and the intentions with which they should be employed. This is evidently owing to the difference which has been long acknowledged to exist in the pathological states constituting the disease, but which has recently been questioned. Without recurring to the changes so fully described above, I may remark, that a person is seized with apoplexy, and, instead of being blooded, is treated with stimulants and restoratives, and yet he recovers without paralysis having supervened. Another person is blooded largely, and he recovers. A third is treated in a similar manner, and he becomes hemiplegic in the course of the attack; and a fourth is also blooded, and he dies. Now these are very common occurrences, and point to very important considerations, which I will pursue a little further. A thin, spare, and debilitated man staggers as he walks, and falls down in the street, with pale countenance, feeble pulse, and laborious or slightly stertorous breathing. He is blooded by the nearest medical man almost immediately, and recovers. A large man, of a full habit and lax fibre, suddenly becomes apoplectic, and is instantly treated with stimulants, and volatile substances held to the nostrils, and his consciousness and voluntary motion are restored in a few minutes. One practitioner of large experience states, that he never draws blood from a patient in apoplexy, excepting under peculiar circumstances, and avers that he is more successful in his treatment than those who do. Another considers that when one full blood-letting fails of giving relief, no benefit will be derived from pushing it further, but much risk of giving rise to paralysis. A third physician equally eminent and experienced, confides in blood-letting almost solely, and carries it often to a great amount; and a fourth, whilst he discards depletion, trusts to stimulants chiefly.

124. But if we examine into their success, we shall find, perhaps, that some difference as to degree may exist; and that, whilst many patients seem benefited, others experience no relief, if they be not even actually injured, by the kind of practice thus exclusively adopted. There is, however, one part of the treatment which is more or less adopted by all: this is the use of purgatives; which, when judiciously administered, are the most generally applicable and beneficial of all the means usually advised. Were it possible to ascertain during life the exact pathological condition obtaining in the various cases of apoplexy, and to convey a correct description of the signs by which each may be known, then the basis for a rational method of cure could be firmly laid; but the skilful practitioner is guided in the treatment he adopts by considerations, circumstances, and appearances, which scarcely admit of de-

scription; and all attempts to impart his knowledge comes far short of his wishes.

125. The method of cure in apoplexy necessarily divides itself into: — 1st, That which is required when an attack is threatened, in order to prevent it, — or the prophylactic treatment; 2d, The means which are to be adopted when the disease is developed; and, 3d, The plan which should be subsequently pursued, with a view of perfecting recovery, and preventing a return of the disease, — or the consecutive treatment.

126. i. THE TREATMENT WHICH MAY BE EMPLOYED TO PREVENT AN ATTACK WHEN IT IS THREATENED. — It is difficult to state the means which may be resorted to with this view, as they ought to be directed with strict reference to the circumstances of the case; which are almost always different, and, not infrequently, even opposite. A strict regard must necessarily be had to the habits, age, and constitution of the patient; the predisposing and exciting causes; and the evidences of previous ailment or existing disorder in remote but related organs. The character of the countenance; the pulse, particularly in the carotids; the temperature of the head; the state of the abdominal functions, secretions, and discharges, must be our chief guides. It should not be overlooked in this stage, any more than when the disease is fully formed; that it may result from nearly opposite states of the vascular action of the brain, and of the circulating system generally; that, although the majority of cases are attended with that appearance of countenance, and action of the arteries, which warrant the inference of existing congestion, retarded circulation, or even increased vascular action in the brain, — there are others, in which the external characters of the head, the face, and action of the carotids, would lead us to infer, either that the vital energy of the organ is so far depressed as to give rise of itself to abolition of the cerebral functions, or that the extravasation of blood and laceration of the structure of the organ has occasioned such a shock to its vitality as to be followed by the same effect on its functions; vascular reaction sometimes supervening in either case, and thus imparting to the attack similar characters to those possessed by seizures which originate in, or are, from their commencement, attended with, vascular turbulence or increased action.

127. In the premonitory state of the disease, it scarcely can be admitted that extravasation or its consequences has occurred, unless in those cases preceded by paralysis; but the signs of incipient congestion, or increased action, are frequently present; whilst also, in many other cases, the symptoms of exhausted or depressed vital power are manifest; this latter state being more frequently antecedent to congestion of the capillaries than is generally supposed, although the fully formed disease may evince inordinate action, with all its usual consequences. Even in the early stage of an attack, this state of the vital power of the organ will often constitute so important a part of the disease, and will yet be attended only by simple congestion and retardation of the circulation, that the use of stimulants may then be beneficially resorted to; whilst soon afterwards, when reaction has supervened, they would no longer be admissible, large depletions, &c. being then required.

128. We should, therefore, endeavour to interpret correctly the origin of the premonitory symptoms, and prescribe accordingly. If the countenance is full or flushed, the eyes prominent or suffused, the pulse of the carotids full or strong; or even if, with this state of the countenance, they are natural; *blood-letting*, general or local, but preferably cupping on the nape of the neck, should be prescribed. If these symptoms have come on after the disappearance of hæmorrhages and discharges, this treatment is still more imperatively required, and should be directed to the restoration of the pre-existing disorder, assisted by other means, such as irritating purgatives, *revelsants*, and external derivatives.

129. When, on the other hand, the action of the carotids is weaker than natural, the countenance sunk, and the head cool, &c., opposite measures are called for: *restoratives*, antispasmodics, and stimulants are here of service, but their use requires caution; for if the pulse in the carotids is full, or strong, or at all above the natural standard, although the countenance be sunk or pale, and if the attack threatens to commence with paralysis, stimulants given internally, or even the outward use of them, as volatile substances held to the nostrils, would be hurtful. In such cases, blood-letting must be resorted to; and a *purgative* of quick operation, assisted by *enemata*, exhibited.

130. There are few cases, presenting even the premonitory signs of an attack, that will not be benefited by a judicious use of *purgatives*, particularly such as are suited to existing disorder of the digestive and biliary organs. In those cases which evince a disposition to vascular excitement of the brain, — where the premonitory signs are accompanied with plethora, heat of the head, injection of the conjunctiva, and flushed countenance, — after depletions and purgatives have been resorted to, the potassio-tartrate of antimony, or *James's powder*, given in moderate doses, and combined with saline medicines, so as to act gently upon the skin or the bowels, and continued for some time, has always appeared to me productive of advantage: but it is only in such cases that antimony is useful as a prophylactic; where, also, *digitalis* may be given with the view of lowering the action; but its use in these cases requires great caution.

131. When the incipient symptoms present much of the character of vital exhaustion of the brain, the combination of purgatives with gentle *stimuli* and *vegetable tonics* and stomachics has proved the most successful in my practice. If the symptoms appear after the suppression of hæmorrhoids, *aloetic cathartics*, or the extract of *colocynthis*, combined with *calomel*, are amongst the best that can be employed; as they tend to induce, by their action on the rectum, a return of the hæmorrhoidal affection.

132. In threatened apoplexy from congestion and impeded circulation through the lungs, heart, or liver, local blood-lettings and purgatives are necessary. In cases characterised by a combination of either of these states with exhaustion or debility, the abstraction of a small quantity of blood by *cupping*, and afterwards *dry-cupping*, issues, or blisters, are sometimes very serviceable.

133. The insertion of setons or issues in the

nape of the neck, or the use of the tartar emetic ointment; and, in very urgent cases, large issues in the scalp of the occiput, particularly when the precursory symptoms evince a paralytic character; cold-sponging the head night and morning, or the shower-bath, with a free state of the alvine secretions and excretions, especially where there is a disposition to congestion, or increased action in the brain, and after blood-letting has been employed; stimulating or irritating pediluvia, or a blister applied to the nape of the neck, and kept open for some time, in similar cases and preceded by the same measures, constitute important items of the preservative treatment.

134. The patient ought carefully to avoid all the predisposing and exciting causes of the disease (§§ 77—87.), particularly crowded apartments, the application of cold to the feet, and violent mental emotions. He ought to sleep with his head and shoulders somewhat elevated; and rise early in the morning. The diet should receive particular attention: it ought to be spare in all cases accompanied with plethora; but not too low, when this state of the vascular system does not exist, and when the vital energies of the brain are already depressed or exhausted. It should, in these latter, be of moderate quantity, and digestible. In all cases, tranquillity of mind and body ought to be carefully preserved; and stimulating beverages avoided, with very few exceptions, which are to be made in favour of those only who present great cerebral and constitutional exhaustion. The beverages for these should be gently strengthening, but not heating, and used in moderation.

135. ii. THE TREATMENT OF THE APOPLECTIC ATTACK.—The patient should be carried into a well-ventilated and spacious apartment, and placed with his head and shoulders very considerably raised, or in a sitting or semi-recumbent posture, with every thing removed from his neck. Directions should also be given to have hot water in readiness. His countenance, state of the eyes and pupils, the degree of fulness, flushing, or pallor of his face, the temperature of his head, state of the pulse in the carotids, and condition of his limbs in respect of sensibility, capability of motion upon their being pinched, &c. ought to be carefully examined; and, according to the evidence thus obtained as to the state of internal lesion, the propriety of depletion, and the extent to which it is to be carried, should be promptly decided on.

136. A. Treatment of apoplexy unattended by depression of vascular action, or by marked exhaustion of vital power.—a. If the pulse be strong, or full, and especially if the countenance be flushed, livid, and tumid, general blood-letting to a large extent, or according to its effect, is to be instantly employed. Much discussion has taken place as to the propriety of opening a vein of the paralysed or non-paralysed side, when paralysis accompanies the attack. ARETÆUS, VALSALVA, MORGAGNI, and CULLEN advise it to be performed in the sound side, whilst BAGLIVI prefers the other: this is, however, a matter of little importance.

137. The next points are the extent to which blood-letting may be carried, and how far certain states of the frame and pulse warrant the practice. In robust, plethoric, and full-living persons,

particularly when the attack has proceeded from exciting causes, and paralysis is not present, thirty or forty ounces may be abstracted at once; and the operation may be performed a second or even third time to a somewhat less extent. When, however, the habit of body is spare, the person far advanced in life, the pulse not full or strong, or little fuller than natural, the heat of the head not increased, and the countenance neither full nor flushed, we must be cautious not to carry it too far. In cases of this kind, local depletions, particularly cupping between the shoulders, or on the occiput, and leeches to the neck and behind the ears, seem preferable. Age is no reason against venesection, if the symptoms indicate its propriety; but very old age, even when the operation is otherwise indicated, is a strong reason for great caution in its performance. In aged persons, local depletions are more serviceable; but even these, employed either indiscriminately or too largely, may occasion a very dangerous, or even fatal, collapse.

138. An intermitting or irregular pulse has very justly led practitioners to hesitate as to the employment of blood-letting. But a single symptom is not to guide us in the use of this, or any other, remedy. If, conjoined to either of these states there be slowness or fulness of pulse, stertorous or strong breathing, constitutional vigour and fulness of habit, tumid, flushed, or livid countenance, blood-letting, even to a very considerable extent—either general or local, or both—may be practised; but when, with irregularity and intermission, the pulse is also small, weak, or quick, the countenance pale, the temperature of the head either not increased, or somewhat depressed, and the respiration weak rather than strong, blood-letting would be highly injurious: a very opposite treatment is then called for.

139. In cases where it is a matter of doubt whether or not general blood-letting should be carried further, or be adopted at all, local blood-letting, to an extent which circumstances will point out, may generally be still employed, and often with great advantage. Vascular depletion being indicated in one form or other, the situation in which it should be performed next remains to be considered. The temporal artery has been recommended to be opened by some: others advise the jugular vein. When the disease arises from congestion, and when the face is livid, the attack strong and the operator expert, the jugular vein may be opened, as sanctioned by VALSALVA, MORGAGNI, HESTER, FRIEND, LANCISI, STOLL, BURSERI, and PORTAL. But undue pressure of the vein, either before or after the operation, must be avoided. Bleeding from the feet, they being plunged in warm water, has been very generally prescribed by Continental physicians; and, in those cases which have occurred after the disappearance or retention of hæmorrhages and periodical discharges, or from metastasis, the practice is very judicious.

140. b. Local depletions in this disease are usually directed on the temples, nape of the neck, or between the shoulders. I prefer the latter situation, as well as cupping, to the use of leeches,—the former being much quicker and more decided in its operation. HIPPOCRATES, ARETÆUS, and MORGAGNI advised cupping to be performed on the occiput: and I unequivocally agree in the

practice. If leeches are applied, the neck, occiput, and behind the ears, are the best situations. LANCISI and CRUVEILHIER advise them to the inside of the nostrils, after general blood-letting, particularly in apoplexy preceded by epistaxis; and WALTHER (*De Apop.*, p. 88.), to the veins near the canthus of the eye. In cases of suppressed hæmorrhoids or menses, the application of leeches to the anus, the anterior part of the insides of the thighs, particularly after blood-letting from the feet, certainly is frequently productive of advantage, even although it very often fails of restoring the suppressed evacuation.

141. Some physicians rely almost entirely on blood-letting, whilst others too frequently discard it. Others more rationally view it as a most important, and a frequently, but not an universally, required remedy. It is by not attending to the pathological states, which I have endeavoured to point out (§ § 108—122.), and to the changes of vascular action which take place during the attack, that such difference of opinion exists, and the indiscriminating practitioner is led to the injurious adoption of one mode of practice only. Among those who prescribe blood-letting almost unreservedly, and to a great extent, I may adduce the respected authorities of CULLEN, CHEYNE, PITCAIRN, COOKE, and ABERCROMBIE; whilst the injurious effects of the practice in many cases, and its applicability to certain states of the disease only, have been ably argued for by KIRKLAND, FOTHERGILL, HEBERDEN, BARBETTE, and DARWIN. There can, however, be no doubt of the propriety of having recourse to vascular depletion in the states of apoplexy now under consideration,—the general character of the symptoms, circumstances of the case, and the effects produced by the first bleedings, being our chief guides as to the extent to which it should be practised. But in the forms of apoplexy characterised by marked deficiency of vital power and action, or sometimes at the commencement of the seizure, when the symptoms, owing to the severe shock sustained by the brain, very closely resemble those of concussion, and before the powers of life recover themselves, and react (§ 111.), blood-letting would generally be attended either with fatal sinking, or with effusion, giving rise to hemiplegia where effusion had, as yet, not taken place, and with a fatal increase of it, in some where it had already existed.

142. *c.* Next to blood-letting, *active purgatives* are most deserving of notice, as being very generally applicable and beneficial. In many of the most severe and sudden attacks it is often difficult, and sometimes impossible, to administer purgatives in the usual form by the mouth. But we may always succeed by mixing from 10 to 15 grains of calomel in sweet butter, and placing it upon the root of the tongue. In some cases two or three grains of powdered camboage may be added to it.

143. *d.* Whilst we are waiting the operation of the purgative, it will frequently be advisable, particularly when there is much heat of head, and action of the carotids, to plunge the feet and legs in warm water and apply *cold to the head*, either in the form of *affusion* of cold water, or of epithem. Great care is necessary not to continue affusion too long, nor to depress the temperature too low, as the risk of inducing hemiplegia will be increased by the practice, particularly

when vascular action is not considerable. After the affusion has depressed the temperature to about the natural standard, cold lotions or epithems, or even frequent cold-sponging, will be sufficient; but increased heat generally returns, and then the affusion should be again resorted to. In general, as soon as the temperature of the head becomes natural, and continues so for some time, and the fulness of the features entirely subsides, cold applications may be omitted. As thus used, they have received the sanction of THILENIUS, CRELL, WEICKARD, CARRETTE, WERNER, and ABERCROMBIE; but QUARIN very judiciously cautions against the indiscriminate and too long continued use of them. CRUVEILHIER, and other French physicians, advise the application of ice for an hour or two, twice or thrice a day, to the head; but, excepting in the more inflammatory states of the disease, it is not required, and may even be attended with risk.

144. If the purgative already exhibited does not operate in about four hours, one or two drops of *croton oil* should be placed upon the tongue, mixed with a few drops of castor oil, or in a little sweet butter, as advised above; and, about an hour afterwards, the action on the bowels ought to be promoted by the following enema:—

No. 20. R Olei Ricini, ℞. Terebinth., ʒʒ. — ʒʒss.;
Decoct. Avenæ, ʒ xij. M. Fiat Enema.

This will generally succeed; but if it come away without feculent or copious evacuations, it should be repeated in from one to six hours, according to the extent of its effect. In obstinate cases, one part of croton oil added to about eight or ten of castor oil may be assiduously rubbed over the abdomen. This, however, will seldom be requisite, as a repetition of the enema will rarely fail, and will act more beneficially on the disease than the introduction of so irritating a substance as croton oil into the circulation. In some cases it may be advisable to render the enemata more irritating by the addition of compound extract of colocynth. Irritating injections are enjoined by ARETEUS, FORESTUS, and many modern authors, particularly THILENIUS. In cases following hæmorrhoids, they are more especially indicated, after leeches have been applied to the vicinity of the anus.

145. After the bowels have been fully evacuated, we must still endeavour to excite the alvine secretions, particularly those of the liver. The region of the liver and epigastrium should be examined: and, if there be fulness there, cupping may be performed in this situation. The calomel may be repeated in smaller doses, oftener than once, and combined with some *preparation of antimony*, or James's powder. In all cases where the apoplectic seizure is attended with increased vascular action, antimony may be given; but sickness or retching should be guarded against. It will be frequently observed that a repetition of the calomel, particularly after full depletions, will be soon followed by a flabby state of the tongue, indicating its incipient action on the mouth, and the propriety of admitting it, and of continuing the purgatives. It is frequently not till now, particularly where the apoplectic seizure has been preceded by much torpor of the liver, and accumulations of viscid bile in the gall-bladder and hepatic ducts, that the purgatives succeed in bringing away dark, greenish black,

offensive motions, the discharge of which is generally followed, in robust subjects, by rapid amendment.

146. *e.* When the disease is attended with *hemiplegia*, or when the paralysis appears in the course of the attack, we may generally presume that extravasation has taken place. In these cases very large or repeated depletions will not much accelerate the removal of the effusion; this is a work of time. The object rather is to arrest the hæmorrhage by the operation; but even this will not be so readily accomplished, owing to the physical condition of the organ. Indeed, if the depletion be carried beyond a certain extent, in relation to the peculiarities of the case, the risk of renewing the hæmorrhage will even be increased; for, as we cannot, as already stated, materially diminish the quantity of blood in the brain, we only accelerate its circulation by large depletions, and thereby risk an increase of the mischief. On this account, therefore, the intentions with which blood-letting is to be employed, are, 1st, to arrest the hæmorrhage, and 2d, to diminish or keep down the action of the heart and arteries: but, although essentially requisite in the majority of cases, full blood-letting will be of itself insufficient to accomplish these purposes; and we have therefore to bring to its aid the application of cold to the head, active purgatives, derivatives, and a judicious combination of antimonials and cooling saline medicines, which ought always to be exhibited at short intervals, and continued for some time during convalescence: two or three grains of blue pill being also taken at bed-time, and an aperient draught the following morning. Any of the following saline medicines may be employed when we wish to lower the action of the heart or arteries of the brain: —

No. 21. *R* Vini Antimonii Potassio-Tart. ℥ xvj. — 3ss.; Liq. Ammon. Acet. ʒ ijss.; Potassæ Nitratis gr. v. — x.; Aquæ Puræ ʒ 3 x.; Syrupi Croci ʒ ss. *M. Fiat* Haustus, tertiâ vel quartâ quâque horâ sumendus.

No. 22. *R* Potassæ Carbon. ʒ j.; Succul Limon. recent. ʒ jss. vel q. s.; Aq. Fœniculi ʒ iij.; Vini Antimonii Pot-Tart. ʒ ij. — ʒ iij.; Syrupi Tolutan. ʒ ij. *M. Fiat* Mist. cuius sumantur cochlearia duo larga, secundâ vel tertiâ quâque horâ.

147. When the measures stated above leave considerable exhaustion, and particularly if accompanied with sopor, weak action of the carotids, a cool state of the head, and unperspirable surface, it will generally be necessary to venture upon the use of very gently restorative and diaphoretic medicines. These ought, however, to be cautiously commenced with; and, when we have reason to infer that the attack has proceeded from extravasation, which is most frequently the case, we should carefully watch their effect, or delay them until after the twelfth or fourteenth day from the seizure. Inflammatory action in the surrounding portion of brain, consequent upon the extravasation, usually supervenes from the fifth to the fourteenth day. During this time, therefore, perfect quietude of body, stillness, and silence, and disengagement of the senses and mental faculties, should be enjoined, and febrifuge medicines prescribed, in order to suppress local action, and the consequent fever which often manifests itself at this period. The patient should be either kept in bed, or on a couch, with his head and shoulders well elevated; and visitors

ought not to be admitted to him. The eighth day is generally the most dangerous, as respects either a renewal of the hæmorrhage, in the immediate vicinity or surface of the parietes of the hæmorrhagic cavity, or in a different part of the brain, or the occurrence of serous effusion between the membranes or in the ventricles. During the first days, therefore, of the attack, we should only venture on the more gentle febrifuge diaphoretics; and after the second or third week, somewhat more restorative means may be employed, if the state of the vital energies requires them. The following may be resorted to in the order in which they are placed: —

No. 24. *R* Potassæ Nitratis gr. v. — vij.; Mist. Camphoræ, Aq. Fœniculi, ʒā ʒ iijss.; Liq. Ammon. Acet. ʒ ij. — ʒ iij.; Spirit. Æther. Nit. ʒ ss.; Syrupi Limonis ʒ ss. *M. Fiat* Haustus, quartâ quâque horâ sumendus.

Before I proceed further, in noticing the other remedies which may be resorted to, or have been recommended, I will state the means which are most appropriate to the weaker states of the disease, and when the system is greatly depressed by the shock of the local lesion, or before increased action has taken place.

148. *B. Treatment of the depressed states of apoplectic seizures.* — It will be apparent from the particular details I have given of the symptoms, causes, and pathological states of the disease — 1st, That much depression or exhaustion of the vital powers of the brain exists in some cases throughout the attack, even rapidly terminating in death without any effort at vascular reaction, particularly when this state is mistaken, and treated by depressing remedies; and, 2d, That this depression is often analogous to concussion of the brain, owing to the extent of the local lesion; and, like this result of external injury, is frequently followed by reaction of the heart and arteries (§§ 111—118.), when the lesion constituting the seizure is not so great as to overwhelm the powers of life.

149. It is owing, in my opinion, either to the employment of too large blood-lettings in some cases, to the having recourse to them at all in others, or to practising them without sufficient regard to this period of the seizure, and before the occurrence of reaction, — the time when they are imperatively called for, — has supervened, that the practice has disappointed many who have adopted it, and led others to employ an opposite mode of treatment in an equally exclusive, and hence dangerous, manner. The judicious use of *gentle stimuli* during this state of depression will have the effect in some cases of bringing about a moderate reaction, when death would be the result of other means; and, by diminishing and shortening the stage of depression in others, and thereby lessening the congestion of the capillaries of the brain, that inordinate degree of arterial action consequent upon the obstruction, and indirectly produced by it, will be prevented. In some more doubtful cases, as when the pallor of the countenance is connected with a natural, or

not very depressed state of the pulse, and temperature of the head, and when there are vomiting and other symptoms, indicating that hæmorrhage and laceration of a portion of the cerebral structure have occurred, blood-letting may be advantageously conjoined with cordial remedies, calculated to restore the tonic contractility of the vessels of the brain.

150. It will appear from what has been stated, that those who deny the efficacy of blood-letting are in some respects justified by the frequent alterations of the vessels and deficient vital energy of the brain, and by the injurious effects of the remedy in some cases, whilst they err in a too general recommendation of opposite means. Both parties, however, place great dependence upon active purgatives, and I believe that much of the success obtained by the abettors of both modes of practice is to be ascribed to them.

151. In apoplectic cases, therefore, with signs of deficient vital energy of the brain and constitution, — and, when we refer to our experience, or consider the nature of many of the exciting causes as well as the very far advanced ages of the great majority of apoplectic patients, the number of such cases will appear by no means small, — and at the commencement of some seizures, before reaction has supervened, when the countenance is pallid or sunk, the pulse of the carotids weak or small, the temperature of the head not increased, and profound sopor, rather than very stertorous or strong breathing, is present, gentle restoratives, administered either internally or externally, are the most serviceable.* The propriety, then, of attending to the fact, that apoplexy often is originally dependent upon the state of the sensorium — upon the depressed vital energy of the encephalon, as well as upon extravasation, or primary or consecutive vascular turgescence, and increased action — is manifest. And hence will appear the reason that restorative measures are required in some cases and not in others, or at one stage of an attack and not at another; physicians being led, by the success obtained from one method of cure on some occasions, to employ

* Travelling in the summer of 1825, in one of the short stages, I sat opposite an aged and corpulent man, who, very soon after our leaving town, suddenly lost his consciousness and power of motion. His countenance became first pale, then bloated and inexpressive, his breathing slow and slightly stertorous, all his muscles completely relaxed, and he fell, in a few seconds, upon those sitting around him. We were only a few doors from a chemist's shop; the coach was stopped, and he was carried thither. He was now profoundly apoplectic; a copious perspiration flowed from his face and forehead, the veins of which were distended, and all his senses were completely abolished. There was no sign of hemiplegia, — but there was general and complete loss of motion and sensation. His neckcloth having been removed, the pulsation of the carotids was found to be slow, and of natural strength and fullness. Whilst he was held in a sitting posture in a chair, cold water was poured gently over his head from a sponge, and his head frequently sponged with it; volatile salts also were held for a short time, and at intervals, to his nostrils. The power of deglutition was at this time abolished, so that it was impossible to administer a draught, chiefly consisting of a small quantity of spiritus ammoniæ aromaticus and camphor mixture, which was prescribed. In a very few minutes his consciousness returned, he took the draught, and in a short time afterwards, he walked to a coach, in which I accompanied him home. He now complained only of very slight confusion of ideas, with scarcely any headache, but his carotids beat more firmly. One full blood-letting, and an active purgative, were now directed. The next day he was perfectly well, and has continued so. What would have been the result if he had been largely bled previously to the reaction?

it too generally, and hence in many instances in which it is inappropriate.

152. The restorative means that may be resorted to, scarcely admit of particular notice. The practitioner must be guided in his choice of them by the circumstances of the case. Where there is sopor, or coma, or lethargy, without much stertor of breathing, and when hemiplegia or paralysis is not present, *camphor* in moderate doses, either alone, or combined with *ammonia* or the *spir. æth. sulph. comp.*, the *tinct. lavand. comp.*, and various others, may be adopted. It is only in such cases, and when the action of the carotids is weak, the head cool, and the countenance sunk, that the *infusions of arnica* or of *serpentaria*, which have been recommended by QUARIN, AASKOW, WERNER, and THOMANN, are admissible. In more doubtful cases, the preparations of *ammonia*, the *spiritus atheris nitrici*, the infusion of *valerian*, may be cautiously exhibited. In some, particularly at the commencement of the seizure, *volatile substances*, such as the preparations of ammonia, and aromatic vinegar, held to the nostrils occasionally, will be of much service. Where the attack is either preceded or accompanied by hemiplegia or paralysis (§§ 31—43.), stimulants, whether exhibited internally, or held to the nostrils, may be more hurtful than beneficial. In these, even the use of cold applications to the head, excepting there be marked increase of temperature, is seldom productive of much advantage. *Purgatives* are, however, required, but the choice and repetition of them should entirely depend upon the state of the secretions, the torpor of the bowels, and the character of the stools.

153. *C. Remedies which have been recommended, and are admissible in certain states of either the sthenic or asthenic forms of attack.*—*a.* *Emetics* are amongst the remedies, the admissibility of which has been most questioned. The young practitioner will, if he have recourse to written authority, be quite bewildered by the diversity of opinions respecting them in this disease. He will find SYDENHAM, PITCAIRN, KIRKLAND, SELLE, FOTHERGILL, COLOMBIER, CONRAD, and FABER, in favour of them; and HAGENDORN, BORSEH, QUARIN, WALTHER, CULLEN, TUESSINK, RICHTER, PORTAL, and CHEYNE, opposed to them. But, when the attack has been brought on by an over loaded state of stomach, by intoxication, narcotic poisons, or other hurtful ingesta, and more especially when hemiplegia is not present, or if the attack be of the active kind, and full depletion has been performed, emetics may be both safely and advantageously administered. This opinion seems agreeable to the recommendations of HIPPOCRATES, MORGAGNI, STOLL, BLANE, and the late Professor GREGORY.

154. *b.* The propriety of having recourse to *blisters* has likewise been questioned. The great majority, however, of authorities are favourable to the practice in some state or other of the disease, the situation, the period, and form of attack, being the chief points of dispute. BARTHOLINUS, CANDLER, CULLEN, and many others, recommend them to be applied to the head. Whilst TODE, BAGLIVI, STOLL, PORTAL, and PICQUE consider them injurious in this situation. In the active states of the disease, in those forms which are complicated with hemiplegia, or are preceded by it, blisters on the head seem hazardous remedies.

dies, and are, moreover, in the way of more appropriate means; but in the weakest forms of the disease, when, from the depressed state of vital energy of the brain and lowered action of the carotids, the sensorium requires to be excited, they may be of service. Where, however, there is any doubt respecting the propriety of applying them in this situation, it will be better to omit them, or to direct them to another part. When stupor or coma exists, and the symptoms are not of the strong character, they may be applied to the nape of the neck, between the shoulders, or insides of the thighs or legs, after general or local blood-letting has been practised.

155. *c.* *Sinapisms*, or *stimulating frictions and liniments*, applied to the lower extremities, are very generally applicable, particularly after resorting to pediluvia, care being afterwards taken to preserve a continuance of the increased flux of blood to these parts, when thus procured, either by warm applications, or by a frequent renewal of the above means. *Sternutatories* have been considered injurious by BAILLOU, MORGAGNI, BUCHNER, and others, and I conceive with great justice. A nearly similar opinion may be given respecting *electricity and galvanism*, which have been recommended to be tried by some authors.

156. *d.* The exhibition of *mercury*, chiefly in the form of calomel or blue pill, in large doses, so as to act upon the biliary secretion and bowels, and subsequently to excite *salivation*, has been recommended by DOLEUS, SCHURIG, GHISI, and HORN. My experience of the practice has led me to think favourably of it in most of the apoplectic states, when the powers of the constitution are not far reduced, and the patient is not very old. *Antimonial preparations* have already been prescribed, and are of much service in the more active or strong forms of the disease, whether accompanied with hemiplegia, or without it. They are not so admissible, however, in the very depressed states of vascular action, and in the forms of attack which commence slowly, or are preceded by, or attended with, paralysis, indicating softening and infiltration of the cerebral substance. *James's powder*, and the *potassio-tartrate of antimony*, are the best preparations; the former of which may be advantageously combined with calomel; the latter with saline medicines. (See R 21, 22, and F. 854.)

157. *e.* *Setons, issues, and moxas* have also been advised, particularly when stupor continues after the more urgent symptoms have been mitigated. I concur with LANCISI and LA MOTTE in considering them very deserving of adoption in such cases. *Moxas* applied on the occiput produce a more rapid effect, and are therefore preferable during the period of attack; setons are more suitable in the prophylactic and consecutive treatment. The *actual cautery* and *moxas* have been strongly recommended by ALBUCASIS, who directed them in the course of the coronal suture; by MARCELLUS DONATUS, who prescribed them to the occiput; by SCHELIAMMER, to the vertex; by SCHREIBER, to both the vertex and soles of the feet; by MISTICHELLI, to the feet; and by THILENIUS and SEVERINUS. These means are very generally applicable, and may be resorted to in the worst cases of apoplexy, particularly those complicated with hemiplegia, and when brought in aid of appropriate means.

158. In cases characterised by a full, tumid, flushed, and livid countenance, full or strong pulse in the carotids, heat of head, with or without hemiplegia, I prefer, after copious general depletion, *scarifications* of the scalp, more or less deep and extensive, to be made over the occiput, so as to allow of a free sanguineous discharge. The practice has been recommended by HIPPOCRATES and MORGAGNI. Cupping glasses may be also applied over the scarifications, when we desire to procure a more copious discharge. In the low or weak states of the disease, *dry-cupping* on the nape of the neck may be tried, as advised by ARETEUS.

159. *f.* After the attack has been so far mitigated that the patient has recovered the faculty of deglutition, I have often seen decided advantage derived from a draught consisting of equal quantities of the *oleum terebinthinæ* and *oleum ricini*, particularly when the bowels required to be fully acted upon. If the attack possess the sthenic character, and signs of fullness of blood about the head still continue, about half an ounce of each may be exhibited on the surface of mint water; and, if necessary, repeated a second or third time, from twelve to twenty-four hours intervening between each dose. This will promote a more complete revulsion from the head than any other means that can be employed, particularly when preceded by calomel, or other cathartics, or followed by the enema prescribed above. (§ 144.) In the weaker states of attack, when we wish the medicine to act partially, by being absorbed into the circulation; and in cases where, from the mode of seizure and progression of the disease, we suspect hæmorrhage or infiltration of blood in the brain, the following draught may be exhibited; I have found it serviceable in such cases, even in some attended with the most unfavourable symptoms; as very frequent, small, and intermitting pulse, and unconscious discharges, &c.:

No. 28. R Olei Ricini, Ol. Terebinth., aa ʒ ss.—5ʒ.; Tinct. Capsici Anni ʒi x.—xvj. Olei Cajuputi ʒi iv.—vi.; Aq. Mentli. Virid. ʒjss. Fiat Haustus, omne biberio sumendus ad secundum, tertium, vel quartum vicem.

In some instances, where the lethargy has been profound, and the constitutional powers far depressed, I have derived much advantage from *camphor, ammonia, and ather*, given in suitable doses in the intervals, and continued after the above medicine had been carried as far as was considered either necessary or prudent.

160. It is generally requisite to have the hair of the patient cut very close, or shaved off, as soon after the seizure as possible; and to attend to the injunction of MORGAGNI, never to omit inquiring after the state of the urinary discharge, and examining the hypogastrium, lest accumulations of urine take place, which should be immediately removed by the catheter, to prevent their injurious effects on the disease, and on the bladder.

161. *D. Of the treatment of the consecutive and complicated states of apoplectic seizures.*—*a.* A great majority of such cases requires but very slight modifications of the measures already stated. The importance of directing our means so as to restore *suppressed discharges*, &c. when the attack arises from this cause, has already been pointed out. When it proceeds from the extension of

inflammatory action to the brain, and its termination in abscess, effusion, &c., the principles stated above are still applicable. If the disease possess either a *gouty* or a *rheumatic character* (§§ 92, 93.), bleeding from the feet, local depletions, sinapisms, or other rubefacient applications, &c. to the lower extremities, or to the joints or parts antecedently affected by gout or rheumatism, active purgatives, and the preparations of colchicum combined with soda, and moderate doses of camphor, are the most advisable remedies. In most cases of this description great accumulations of morbid sordes have formed on the digestive mucous surfaces, and thick or viscid dark bile in the gall-bladder and hepatic ducts; therefore, after cupping on the nape of the neck, active calomel purges, promoted by enemata, are to be given, previously to having recourse to *colchicum*, which ought to be combined with alkalies, — with *ammonia* or other restorative medicines, if the attack presents the asthenic character, and with aperients: active *revulsants* being simultaneously employed.

162. *b.* When the apoplectic state arises from *erysipelas* of the head and face, incisions made into the scalp of the occiput, so as to allow a free discharge; cupping on the nape of the neck; active purgatives, consisting first of calomel combined with the potassio-tartrate of antimony or with James's powder, and compound extract of colocynth, followed by the draught of turpentine and castor oil advised above (§ 159.); and saline medicines, with the *vinum antimonii*; are the means most to be depended upon. In cases of this description the most active purgatives are required, and must be frequently repeated. The croton oil may be here exhibited, as already advised (§ 144.), and enemata should be administered from time to time. These already prescribed (§ 144.), or F. 141. 151. are most to be depended upon in this state of disease. *Revulsants*, and rubefacient pediluvia, are also serviceable aids.

163. *c.* When the apoplectic attack occurs on the invasion, or in the advanced stages of *fevers* (§ 94.), the general principles of treatment already laid down cannot be departed from. When it comes on at the commencement of fever, general or local depletions are required, with cold affusion to the head, purgatives, saline medicines, and counter-irritation. But even here, the probable state of the circulation within the head should be inquired into previously to the adoption of the means of cure; for, if the head be cool, the action of the carotids natural or below the healthy standard, and the attack be unattended by paralysis, restorative measures are called for, although the subsequent occurrence of reaction will afterwards require active antiphlogistic measures. When the attack occurs in the last stages of continued or eruptive fevers, it most frequently presents the asthenic character, and is often an aggravated state, or a modification merely, of coma, unless hemiplegia accompany it. In these cases, local depletions from the occiput, the neck, and behind the ears; active purgatives; *revulsants*, and counter-irritants, as blisters or sinapisms to the lower extremities, nape of the neck, or epigastrium; camphor, combined with ammonia, æther, and liquor ammonia acetatis, particularly when the head is cool, and the puls-

ation or the carotids is neither full nor strong; and, in the most asthenic cases, camphor in larger doses, the infusions of arnica, or of serpentaria (F. 222. 262.), are chiefly to be depended upon. After local depletions and *revulsants* have been prescribed, and one or more doses of calomel and rhubarb premised, the draughts directed above (R. 23. 26, 27, 28.), or F. 270. 863., followed by enemata (F. 138. 149.), may be exhibited.

164. *d.* The association of apoplectic seizures with disorders of the *digestive organs*, particularly those of the liver (§§ 97, 98.), requires local depletions from the right hypochondrium and epigastrium, followed by blisters in this situation, and a strenuous use of purgatives and mercurial preparations, until the secretions assume a healthy appearance. When the attack proceeds from impeded circulation through the lungs and right side of the heart (§§ 95, 96.), local depletions, counter-irritation, and diaphoretics, are chiefly to be depended upon. But in these cases care must be taken not to deplete too much, as the circulation may be still more impeded by the loss of power thereby produced. In some instances of this kind, it will even be necessary to support the vital energies by suitable means, and to deplete the vascular system at the same time. When the attack is occasioned by hypertrophy of the left ventricle, general and local depletions are better borne than in the foregoing cases, and may be carried to a considerable extent. In both descriptions of cases, *revulsants* and counter-irritants, particularly by issues, and the tartar emetic ointment, are beneficial.

165. *e.* When the attack is occasioned by *narcotics* or *spirits* taken in immoderate quantities, the stomach should be emptied by the stomach-pump, or by an emetic, a moderate blood-letting having been premised; and afterwards, the cold affusion to the head; internal stimuli, as camphor, ammonia, and æther; warm, strong coffee; and purgative enemata, should be prescribed. The occurrence of the seizure, also, during *child labour*, or after *epileptic* or *hysterical* convulsions, requires large blood-lettings, preferably from the feet, the cold affusion to the head, cathartic injections, &c.*

166. Attacks consequent upon *colica-pictorum* (§ 99.), two instances of which have occurred to me, generally require local depletion, full doses of calomel, followed by active purgatives and enemata (§ 142.). The draught of castor oil and turpentine (§ 144.), or the croton oil followed by injections, are here chiefly to be confided in. If purgatives given by the mouth are thrown off the stomach, — a circumstance which not infrequently occurs in these cases, — a large dose of

* I was called in 1826, in consultation, to a case of puerperal convulsions which had terminated in the apoplectic state. When I saw the patient, the labour had not proceeded so far as to admit of delivery by means of instruments. The pulse was slow and full; the breathing slow, laborious, and stertorous; the lips puffing and frothy, the countenance tumid and livid; all the limbs flaccid, insensible, and incapable of motion. She had been bled largely before I was called. The feet and legs were directed to be placed in a pan of hot water, and the saphena veins to be opened. Whilst the blood flowed, the cold effusion on the head was employed. These means were evidently beneficial, though insufficient. A cathartic enema (F. 149.) was thrown up immediately, and with great difficulty; consciousness slowly returned; when the decoction of the scale cornutum, with as much biboras sodæ as it could dissolve, was administered. Uterine action afterwards came on, and the patient recovered.

calomel will generally be retained; and will allay the irritability of the stomach: other medicines may be afterwards exhibited, or a mixture of croton and castor oils rubbed over the abdomen, and cathartic injections thrown up. The other states and complications of the disease must be treated according to the views and principles already explained, and with due reference to the nature of the pre-existing disorder, when it appears to be a consecutive affection, or a principal part of a complicated state of disease.

167. iii. TREATMENT SUBSEQUENTLY TO THE ATTACK, OR THE CONSECUTIVE TREATMENT.—The symptoms consecutive of apoplexy have a strict relation to the changes which take place in the seat of lesion. The absorption of the blood, and the process of cicatrization, require several months for their completion. During this time great care should be observed to prevent inflammatory action from taking place around the extravasated blood, and a return of the hæmorrhage. This object is best attained by adopting very nearly the same measures as have been recommended to prevent the accession of the attack (§ 126. *et seq.*). A too sedentary or studious mode of life, watchfulness, much indulgence of sleep, frequent stooping, and all the remote causes of the disease, must be carefully shunned. The strictest temperance and moderation, in respect both of eating and drinking; moderate exercise in the open air; tranquillity of mind, sedulously avoiding the least approach to bodily or mental fatigue, and excitement of the feelings or passions; the preservation of a free state of the alvine secretions and excretions, by means of mild and deobstruent purgatives and cathartic enemata; general or topical blood-letting, particularly every spring and autumn, with low living or a vegetable diet, when there is a tendency to vascular plethora; caustic issues, or setons in the nape of the neck, or in the course of the cervical spine; the use of the tartar emetic ointment, so as to keep out for a considerable time a pustular eruption on the part to which it is applied; sleeping on a hair mattress, with the head and shoulders slightly elevated, and early rising; are amongst the most efficacious means that can be adopted.

168. For persons who are prone to plethora, in addition to periodical depletions and low diet, the following pills and electuary may be taken on alternate nights:—

No. 29. R. Pilul. Hydrarg. Chloridi Comp. gr. iij.; Pulv. Jacobi Veri gr. ij.; Saponis Castil. gr. iv. M. Fiat. Pilule ij. h. s. s.

No. 30. R. Potassæ Bi-tart. ʒ. j.; Sodæ Bi-carb. gr. x. (vel Magnesie ʒ. i.); Confectionis Scam. Syrup. Zingiberis, aa ʒ. j. M. Fiat Electuarium, pro dose, horâ somni, alternis noctibus sumendum.

169. When the disease is connected with the gouty diathesis, vegetable diet, the carbonates of the fixed alkalis, with the extract of tuxacum or the preparations of aloes, the occasional use of an active cathartic, and the other prophylactic measures recommended in the article on Gout, are requisite. In all cases, as much benefit will now accrue from a strict attention to regimen and diet, as from medicine. The food should be light and digestible, of very moderate quantity, chiefly farinaceous, and taken at regular hours. Suppers should be avoided, or be extremely light, and taken a considerable time before the usual hour of repose. Fish, and ripe fruits, may be partaken

of in moderation; and the waters of Cheltenham occasionally tried, or the following used as a substitute:—

No. 31. R. Magnes. Sulph. ʒ ss.; Potassæ Sulph. ʒ ij.; Infus. Rosæ Co. et Mist. Camphoræ aa ʒ iijss. M. Capiat Coch. iij. amplâ primo mane quotidie.

170. After attacks of the more asthenic states of apoplexy, a more tonic regimen than that directed above may be adopted; but it should be conjoined with the same attention to the digestive, secreting, and excreting functions. Attacks of this description most commonly proceed from depressing or exhausting causes, which ought either to be avoided or counteracted; and when they are not characterised by plethora, or disposition to increased action, gentle tonics combined with aperients, a light strengthening diet, the occasional use of the preparations of *strychnine*, or *iodine*, as recommended in the article on Palsy, and the mineral waters of Bath, Leamington, or Buxton. The following may also be occasionally taken:—

No. 32. R. Potassæ Sulphatis ʒ ij.—3 iij.; Infus. Rosæ Co. ʒ iijss.; Acidi Sulphur. Arom. ʒ j.; Tinct. Aurantii Co. ʒ ss. M. Capiat Coch. iij. amplâ primo mane.

171. In all cases of the consecutive treatment, the progress of the paralytic or hemiplegic affection towards removal should receive attention. In the more favourable cases, as the period of attack recedes, first sensation, and afterwards motion, return in the paralysed limbs; and generally the lower extremity experiences the amendment before the upper. As recovery proceeds, the patient should always wear his hair cut short, and sponge his head with spring water night and morning. In summer he may use the shower bath daily, if he be not far advanced in life or much debilitated. As much of the treatment described in the article Palsy, as may suit the circumstances of the case, may also be adopted for the removal of this common sequela of the attack. (See also ASPHYXY, and POISONS.)

APOPLEXY OF NEW-BORN INFANTS—1. Generally proceeds from a protracted or difficult parturition, particularly when the infant is large and plethoric, or when the chord has passed around the neck, occasioning both interrupted circulation in the chord, and obstructed return of blood from the brain. The apoplectic state in new-born infants is accompanied with tumefaction of the face, head, and neck, which, with the whole surface of the body, is generally of a bluish or violet colour. The muscles are flaccid, the limbs flexible, and the body warm. The pulsations of the heart and of the chord are generally obscure, or not to be felt; respiration is suppressed; and death soon takes place, in extreme cases, if judicious means of restoration be not resorted to.

2. Upon examination of fatal cases, the vessels of the encephalon are engorged with blood; and occasionally blood is extravasated in the substance of the brain, or between the membranes. The lungs are also generally congested. It is evident that the pressure of the turgescient vessels and extravasated blood upon the brain, and origin of the respiratory nerves, prevents the respiratory actions from taking place, and that all attempts to excite respiration will be ineffectual until the pressure is removed. The umbilical chord should therefore be immediately divided and allowed to bleed to the extent of two or three spoonfuls, according to the size and strength of the infant. When the apoplectic state is occasioned by congestion of the vessels merely, respiration will take place as soon as the vessels are unloaded, if no mechanical obstacles to the entrance of air into the lungs exist. Mucosities should be carefully removed from the throat,

mouth, and nostrils; and, if the respiration does not spontaneously take place, insufflation of the lungs, as recommended in the article on *ASPHYXY of New-born Infants* should be performed.

3. When the circulation is so torpid that the blood will not flow from the portion of umbilical chord attached to the infant, the little patient should be placed in a warm bath, rendered more stimulating by some salt, or by a little mustard; the portion of chord attached to the abdomen, or the abdomen itself, may be pressed momentarily, at several times, and in the direction of the division. If these means fail of procuring blood, one leech may be placed behind each ear. In some cases the apoplectic symptoms return after respiration has been established. This is generally owing to some interruption to the circulation through the lungs. In these cases of secondary attack, the application of one, or generally two leeches, placing the body or the lower part of it in a warm bath, and, if requisite, inflation of the lungs, and the other measures advised in the article on *ASPHYXY*, must be resorted to; and they will be successful if the case admit of recovery.

APPETITE, MORBID.

CLASSIF. 5. *Class*, Local Diseases; 2. *Order*, Depraved Appetites (*Cullen*). 1. *Class*, Diseases of the Digestive Functions; 1. *Order*, Affecting the Alimentary Canal (*Good*). II. **CLASS**, 1. **ORDER**, (*Author*).

1. **DEFIN.**—*Excessive craving for food, or desire for improper substances.*

2. In this genus may be included *two* species, viz. 1st, *Excessive or insatiable craving for food*; and, 2nd, *A desire for improper substances, or what is not food*. These states of function occur in practice variously associated; and although apparently different in themselves, yet they are often individually connected with similar states of the constitutional energies, and dependent upon nearly the same state of lesion, whether functional or organic. It would seem that manifestations of function often differ most essentially, in different persons, or under different circumstances, owing to causes which are so slightly dissimilar as not to admit of distinction or even, in some cases, to appear very nearly the same. In all, or the great majority of cases, belonging to these forms of morbid function, the general pathological states of the system are nearly the same; the difference, even when it is most marked, being chiefly referrible to variations in grade, and to states of the stomach, in respect of its sensibility, its secretions, tonic contractions, and states of its villous membrane, which can only be matters of inference, but seldom of demonstration. As regards their nature, these affections are much more frequently *symptomatic* of lesion of function or structure in some other organ, than *idiopathic*, or constituting primary disease of the stomach itself.

3. **SPEC. I.** **INSATIABLE APPETITE.**—**SYN.** *Bulimia* (from βού, the augmentative particle, and λιμός, hunger), *Fames Canina*, *Limos avis*, *Good*, *Bulimus Polyphagia*, *Lycorexia*, *Cynorexia*, *Auct. Lat.* *Faim Canine*, *Fr.* *Der Heisshunger*, *Ger.* *Dyspepsia Bulimia*, *Young*, *Gluttony*, *Canine Appetite*.

4. **DEFIN.** *A craving for food beyond the*

natural wants of the system, sometimes most excessive in degree.

5. *i. VARIETIES.* An inordinate appetite is sometimes observed in the course of fevers and other acute diseases, particularly in convalescence from them; and in the progress of a number of chronic diseases. It is not infrequent in cases of extreme exhaustion, from whatever cause; and it may depend upon an acquired habit. But in order to consider it with some degree of precision, I will offer some remarks, 1st, upon habitual indulgence in an excessive quantity of food, or gluttony; 2d, an insatiable appetite from exhaustion; 3rd, on the excessive appetite, which, from the extreme voracity of the patient, has been called canine; and, 4th, on the voracity which is followed by vomiting. These constitute varieties of nearly the same disease.

6. *A. Habitually excessive appetite, the Bulimia Heliconum of CULLEN.*—In some cases, the excessive indulgence of food has been of so long duration, and seemingly attended with so good a state of the general health, as not to appear in the light of a disease; but the results ultimately are the production of so great vascular plethora, and disorder of the secreting functions, that, as soon as the vital energies begin to languish, apoplectic, paralytic, or other maladies supervene. This variety of morbid function may be hereditary, but it is oftener acquired. It is not infrequently observed in persons, originally of a strong constitution, who have indulged in large and frequent meals from having little else to engage their minds; and thus the vital energy has become concentrated towards the stomach and the rest of the digestive organs, exalting all their functions. Persons of this description usually become large, bulky, or corpulent; and if they take much exercise, the great indulgence of their appetite may not materially shorten their lives; but when sedentary habits and indolence are conjoined with it, apoplexy and organic disease of the liver, stomach, bowels, &c. are the common results.

7. *B. Inordinate appetite from exhaustion.*—This is often a symptom of other diseases, and is chiefly dependent upon altered sensibility of the nerves of the stomach, proceeding from weakened vital power. In many cases, however, it appears as the chief ailment, as after great fatigue of body and mind; after excessive venereal indulgences; in cases of great emaciation, sometimes without any evident cause; and during convalescence from fevers and other acute diseases. It is very often observed as an attendant upon organic diseases of the stomach, pylorus, mesenteric glands, liver, uterus, &c. It has also been remarked in cases where due nourishment could not be conveyed into the system, owing to disease of the absorbent system; and it is frequent in the last stages of chronic maladies, when about to terminate fatally. In many of such cases the craving for food is attended with a distressing feeling of inanition, sinking, and faintness. Some of the cases of excessive appetite that occur in pregnancy, or from the presence of worms, may also be referred to the debility and altered sensibility of the nerves of the stomach. And those which accompany inanition from a defective supply of chyle to the blood, may be attributed partly to the same cause, and partly to the instinctive wants of the system.

8. *C. Voracious or canine appetite, the Bulimia Sycopolalis of CULLEN.*—This extreme form of the disease is generally dependent upon some organic change of the stomach; but this is more a matter of inference than of observation. The chief seat of disease may even be some other organ. The quantities of food, particularly animal food, cooked or raw, taken by some persons afflicted by this disease, are truly surprising.* One of the most remarkable cases in record is that published by M. PERCY (*Dict. des Sciences Méd.*, art. CAS. RARES). Both CULLEN and GOOD are incorrect in stating that this form of Bulimia is attended with faintness. This is only an occasional symptom, which was absent in both the cases that occurred to me, as well as in that recorded by Dr. CRANE. (*Lond. Med. Repos.*, vol. xvii. p. 293.)

9. *D. Voracious appetite followed by vomiting, the Bulimia Emetica of CULLEN.*—This variety of bulimia frequently proceeds from inflammatory irritation about the pylorus, but more commonly of the mucous surface of the stomach itself. The quantity of food devoured in this description of cases is often as large as in the last variety; but shortly after having been taken, it is either altogether, or in part, thrown up, very little altered, and thus the patient continues alternately to crave for and to reject his food. This form of the disease has generally been imputed to a scirrhous state of the pylorus; but the case of Dr. CRANE, already alluded to, was evidently independent of such a cause.

10. *ii. CAUSES.*—*a.* The remote causes of bulimia are chiefly hereditary predisposition; the habit of eating largely, voraciously, and without due mastication; chronic debility, arising from obstruction of the mesenteric glands, liver, &c.; the suppression or disappearance of chronic eruptions, the healing of old ulcers, or the suddenly arresting habitual discharges, and the pathological conditions noticed in the foregoing remarks.

11. *b.* The immediate cause, or state of the organ on which it depends, seems to be somewhat different in the different varieties, even whilst the state of the constitutional or vital power may be considered to be, in the great majority of cases, very nearly the same. I believe that in many instances the voracious appetite is owing to an

* I have met with two very remarkable instances of this affection in children, — the one of seven years of age, the other of nine. In both these, but in the younger especially, the quantity of food devoured was astonishing. Every thing that could be laid hold of, even in its raw state, was seized upon most greedily. Besides other articles, an uncooked rabbit, half a pound of candles, and some butter, were taken at one time. The mother stated, that this little girl, who was apparently in good health otherwise, took more food, if she could possibly obtain it, than the rest of her family, consisting of six besides herself. In both this and the other case, the digestion seemed to be good. Three or four large feculent motions were passed daily, and a nauseous smell emanated from their bodies. These children, who were both very intelligent, complained of no other uneasiness than a constant gnawing or craving at the pit of the stomach, which was never altogether allayed, but which, shortly after a meal, impelled them irresistibly to devour every thing that came in their way, in the shape of food, however disgusting. Nearly twenty years ago I saw, for a short time, a case of this description, which occurred in a child of about the same age, and occasioned alarm, owing to the circumstance of a large quantity of raw fish having been devoured by it. The result in this case did not come to my knowledge; but the former cases, which occurred at the Infirmary for Children, recovered by means of the treatment which will presently be noticed.

irregular distribution of the vital energy, and its concentration in the stomach, the nerves of this viscus being morbidly sensible, the muscular coats more irritable, particularly in the fourth variety of the disease; and the mucous coat in a state of erythema, or vascular excitement, and yielding a much larger quantity of its proper fluids than in health. The excited state of the nerves of the organ will necessarily be followed by increase of its secretions, greater vascularity of its inner coat, and a disposition of the muscular tunics to react upon the enormous quantity of food which distends them; and thus there will result the craving of extreme hunger, a rapid solution of the food, and a quick transfer of it into the duodenum; or, if the reaction takes place suddenly, either vomiting or simple regurgitation of it, as in cases of *rumination*, which is sometimes *complicated* with bulimia. The more remote effects of this state of the organ are, torpor, debility, and a sense of faintness arising from the concentration of the vital energy, and determination of the circulation and secreting function towards the stomach and associated viscera, and the proportionate abstraction of vital influence from the brain and heart; imperfect assimilation; irritation of the digestive mucous surface, from unwholesome and unchanged food; an impure state of the blood, disorder of the secreting organs and morbid secretions,—all tending to disorganization, and to the destruction of life.

12. *c.* The *morbid appearances* found on dissection consist chiefly of inordinate distension of the stomach and duodenum; a vascular and corrugated state of their mucous surface, constituting complete hypertrophy of these viscera; a flabby, softened, and sometimes thickened appearance of all these tunics (HAGSTROEM); displacement of the right extremity of the greater part of the stomach low in the abdomen (FRENCH); induration and thickening of its coats (Goudret); the insertion of the common bile-duct into its pyloric extremity (VESALIUS and BONET); dilatation of the oesophagus (SCHURIG); tænia in the bowels; lumbrici in the stomach and duodenum; enlargement and other organic lesions of the liver: scirrhus, thickening, and even dilatation (RUYSEN), of the pylorus; thickening of all the coats of the duodenum, forming hypertrophy of this part; and various organic changes in the mesentery, its glands, the pancreas, spleen, and very generally in the mucous surface of the small and large intestines. M. BECLARD observed, in a case of bulimia, the *valvula conniventes* as large as in carnivorous animals. And M. LANDRE-BEAUVAIS found, in a case complicated with pulmonary consumption, an unusually large size of the small intestines, and the gall-bladder wanting.

13. *d.* *Symptomatic bulimia.*—Inordinate appetite has sometimes been observed in cases of chronic disease of the brain, particularly in slow inflammation of its substance, threatening, or terminating in, insanity. A very marked case of this description, and two or three slighter instances, have come before me in the course of practice. I have also met with it at the commencement of hydrocephalus, and in epilepsy. When thus dependent upon disease of the brain, the inordinate indulgence of the appetite is often followed by vomiting. In the case of epilepsy, however, in which I met with it, vomiting never

took place, although the quantity of food sometimes taken was most excessive. The first, or slighter variety of the malady, is not uncommon in epilepsy, particularly in the hereditary epilepsy of adults; the second variety sometimes occurs in hysteria, chlorosis, and pulmonary consumption; and the fourth, occasionally, in chronic encephalitis.

14. Bulimia is more frequently met with, particularly in its slighter forms, in pregnancy and in verminous affections, and is then very generally attended with an urgent feeling of inanition and faintness. When it occurs in pregnancy, there is usually a fanciful longing for particular articles of food, of which an enormous quantity is devoured. A remarkable excitement of the nerves of the stomach may be inferred to exist in these cases, greatly augmenting the secretion of gastric juice. When the affection proceeds from worms, it may be imputed to the irritation of the nerves and mucous surface of the stomach and duodenum, whereby the circulation of, and secretions poured into, these viscera, are much increased, whilst the vital actions of the rest of the frame languish more or less.

15. *iii.* *TREATMENT.*—The means of cure should have strict reference to the immediate cause to which we attribute the disorder. *A.* In the *first variety* of the disorder, it is generally in vain to state any means of cure. They entirely rest with the patient, by whom medical advice will seldom be followed. I have great doubt of a single glutton having been deterred from the habit he has acquired, by the injunctions of his medical adviser, until an attack of illness occasioned him alarm. The cure is sufficiently simple, and may be comprised in the single recommendation of employing his mind and body more, that he may abuse his stomach less.

16. *B.* In the *second variety*, great attention is required to adapt the treatment to the circumstances in which it presents itself. The nature of the malady of which it is most commonly a symptom, must necessarily be our guide; and as the means should be strictly appropriated to the peculiarities of the case, no general rules can be stated with propriety, further than that the effects of whatever is employed should be carefully watched, and that more mischief will result from indulging the craving complained of, than from opposing it, and allowing no more nourishment than the nature of the case, or the system, may seem to require. In the bulimia that occurs in convalescence from acute diseases, the wants of the economy are generally greater than in other cases, and here more may be allowed; if fever or disorder follow the indulgence, a purgative will generally remove it.

17. *C.* The preceding observations apply likewise to the *third and fourth varieties* of this disease. The cases which occurred in my practice were cured by an active course of nauseating purgatives, consisting chiefly of the oil of turpentine with castor oil. In one of the cases, where the voracity was almost incredible, the first dose of the turpentine was followed by the sudden appearance, over the whole trunk of the body, of a most copious and thick eruption, more nearly resembling porrigo favosa than any other, and by the equally sudden relief of the symptoms. This treatment was left off; when, after a few days, the eruption disappeared, and the voracious ap-

petite returned. It was ultimately removed permanently by the hydrarg. cum cretâ, combined with soda, taken at bed-time, and a turpentine draught in the morning of each third or fourth day. Leeches were applied over the epigastric region; and either the tartar emetic ointment, or liniment, was rubbed upon the same situation till a copious eruption of pimples was produced. The strictest regulation of the diet was enjoined.

18. *D.* In the variety attended with partial or general *ingurgitation*, or vomiting of the food taken in excessive quantity, the best effects will result from obliging the patient to abstain almost altogether from food, or to take a small portion of nourishment in the least possible bulk. Great distress from hunger will be felt for a few days, but this will gradually subside. In the instructive case published by Dr. CRANE, this plan was persisted in; and portable soup, made into pills, was given, as the only nourishment, for several weeks: the patient recovered perfectly. A nearly similar treatment had been previously employed by Mr. WASTELL with success. (*Mem. of Med. Soc. of Lond.*, vol. iii. No. 2.) Where, however, the stomach is not so irritable as to throw off any portion of the ingesta, and has become distended and enlarged from habitual *ingurgitation*, a gradual diminution of the food will be better borne, and perhaps be more efficacious, than its sudden reduction. The propriety of employing deobstruents, small doses of the blue pill, combined with ipecacuanha, active cathartics, either by the mouth or in the form of enema, and external irritants and revulsants, in cases of this description, cannot be questioned. Exercise, where it can be taken; and employment for both body and mind, as far as circumstances will permit; are also most useful adjuncts.

SPEC. II. VITIATED OR DEPRAVED APPETITE.

—*SYN.* PICA, *Citta*, *Malacia*, *Pseudorexia*, *Iimoxis Pica*. Good. *Dyspepsia Pica*, Young. *Der Sonderbare Appetit*, Ger.

1. DEFIN. *An appetite for substances which are not food.*

2. i. CAUSES.—This state of the appetite sometimes occurs in children, from an early acquired habit; and it is frequently observed in idiots, from want of ability to discriminate what is or is not food, or from perversion of taste. Various substances also, which are abhorred in one climate, constitute the chief articles of diet in another. Thus, the Californians live on snakes, rats, lizards, &c., and numerous tribes of Africans on monkeys, dogs, snakes, &c. It is very frequently observed in pregnant, hysterical, and chlorotic females, and it is sometimes connected with certain kinds of mental emotion. I have met with several instances of it in females at the age of commencing puberty, when neither hy-

steria, in any of its forms, nor chlorosis, existed. In these, and perhaps in the great majority of cases, it is altogether a symptomatic affection, arising from altered sensibility of the nerves, and modified state of the secretions of the stomach, occasioned by imperfect function, or changed condition, of a related organ, particularly of the uterus, ovaries, large bowels, and brain.

3. When it is observed as the primary disorder, it has generally been owing to a habit, commenced at first with the view of improving the shape and complexion. Females early in life sometimes have recourse to acids, particularly vinegar, and chalk, for this purpose. The form of the disease, which has been described by Dr. JOHN HUNTER as dirt-eating, by the negroes in the West Indies, and which has even assumed an epidemic character, is, perhaps, more than other forms of it, deserving of being considered as idiopathic. The earth they devour chiefly consists of a loam or clay, and may possibly be taken by them from the circumstance of their having found it assuage the painful sensations produced in the stomach by acidity. This affection is much more frequently met with in the female than in the male sex; but instances of its occurrence in the latter are not rare. I have seen several instances of it in males; and in females it is often practised in so concealed a way, as not to come to the knowledge of the medical attendant.

4. The substances which occasionally become the objects of desire are sufficiently numerous. Medical records abound with them. Cinders, spiders, lice, flies, insects, toads, serpents, wood, hair, paper, earth, clay, chalk, vinegar, and other acids, and even ordure, have all been devoured in cases of this disease. Various other substances have been swallowed, more as singular exploits than from actual longing for them. Thus we have accounts of persons taking into their stomachs clasp-knives, musket bullets, billiard balls, gold watches, and Louis-d'ors; and, what is still more singular, generally discharging them by stool a few days afterwards. Knife-eating seems to have been no uncommon feat, as we have instances recorded of London, Prussian, Bohemian, North American, and Brazilian knife-eaters. Our friends of the United States seem to have surpassed all others in the rapacity which their knife-eater exhibited; for in June, 1822 (*New York Med. Repos.* Oct. 1822), after having been duly initiated in the art, by swallowing a gold watch, chain and seals, billiard balls, and various other articles, at different times, which had passed through his callous digestive tube, he swallowed fourteen knives in the course of the day. This was his great, but his last exploit, for he died two months afterwards; having passed two of the knives by stool, the remaining dozen being found in the body,—eleven in the stomach, and one in the œsophagus.

5. The articles most commonly fancied by young females are paper, cotton, thread, chalk, vinegar, and other acids. I once saw a sickly-complexioned lad, who was in the habit of eating sand; and a robust seaman, who occasionally would devour a whole wine or ale glass, having previously crushed it in small pieces with his teeth, and yet no bad effects resulted, at least for many months afterwards (*Lond. Med. Repos.*, vol. xviii.). The only other instance on record, where this most danger-

ous feat has been performed, is given by CAME-
RARIUS (*Memorab. cent. v.*).

6. When *pica* is complicated with *bulimia*, as is sometimes observed, most singular and even astonishing feats in the way of devouring substances of the most unsuitable kind are on record, — many of them also so large, that the possibility of their being conveyed into the stomach, if they had not actually been found there, might have been doubted. Some really astonishing and authentic instances of this kind have been related by M. FOURNIER (art. CAS. RARES, *Dict. des Sciences Méd.* t. iv. p. 135.).

7. ii. TREATMENT. — The means of cure must, of course, have strict reference to the morbid condition of the system, of which it is so frequently a symptom. If it accompany pregnancy, I believe that the axiom which M. FRANCIER adopts as the title of a treatise on the subject should be adopted, viz. A pregnant woman affected with *pica* should be well purged. If it be attendant upon *chlorosis*, *aloetic purgatives*, with *emmenagogues*, and these followed by or given alternately with *tonics*, are the most suitable means, and are equally beneficial in the *pica* which occurs about the period of puberty. In *hysteria*, similar measures, combined with *valerian*, *assafoetida*, *camphor*, and other antispasmodics, are indicated. In these three symptomatic forms of the disease, any of the Formulæ for those medicines in the Appendix may be adopted.

8. When the affection presents an idiopathic character, which is comparatively rare, it is most commonly owing to a weakened state of the digestive organs, with, perhaps, an altered sensibility of the nerves, and acid state of the secretions of the stomach. In these cases, the combination of vegetable tonics with alkalies, and attention to the alvine secretions and excretions, are chiefly required. The treatment of cases of the affection induced early in life from habit, will be unsatisfactory, or without avail, until the cause is removed; but it differs in no essential particular from that now stated. In many cases the pernicious habit has commenced with early puberty, and, as well as in the cases associated with *chlorosis*, *hysteria*, pregnancy, and irregularity of the menstrual discharge, is evidently dependent upon the state of the uterine functions. (See CHLOROSIS, MENSTRUATION.)

ARTERIES, THEIR DISEASES. — SYN *Arteria*, Gr. *Arteria*, Lat. *Artère*, Fr. *Eine Schlagader*, Pulsader, Ger. *Arteria*, Ital. *Artery*, Eng.

1. The morbid conditions of arterial vessels cannot be appreciated, either in respect of their causes, symptoms, or consequences, unless their organisation and connections with other systems of the frame be clearly understood. It does not fall within my limits to notice all the connections which these vessels present with other parts of

the body; but there are a few to which I will briefly allude, as most material in the causation of their diseases, and of certain sympathetic affections with which these diseases are related.

2. I. ORGANISATION. — The arterial tubes are essentially constituted, 1st, Of an *external* and *adventitious tunic*, consisting of a very delicate and condensed cellulose-filamentous tissue. This tissue is never infiltrated by serum, nor loaded by fat; and possesses the greatest degree of resistance of all the other coats of the vessel. 2d, Of a *proper coat*, consisting of fine circular fibres placed closely together, and forming a strong tissue of a dun yellowish colour. The nature of this tissue has been a matter of much dispute with pathologists. It certainly does not possess the physical and chemical properties of the fibres of voluntary muscles, from which it chiefly differs in being much more close in its structure, and more elastic and fragile than they. 3d, Of a very delicate cellular tissue, like a fine pellicle, the *second cellular tunic* of HALLER, interposed between the fibrous or proper coat and that next to be described. It is in this fine membrane that the minute vessels supplying the arteries, and which proceed from the adjoining parts, terminate; and here also the ultimate distributions of the arterial nerves may be supposed to ramify, although they cannot be clearly traced further through the coats of the vessel than the proper fibrous tunic where I have distinctly followed them. This is the most vascular of the tunics strictly constituting arterial vessels; and one in which many of those changes which will fall under consideration commence. 4th, Of an *internal membrane*, presenting no linear or fibrous structure, semi-transparent, more readily detached from the one next to it in the longitudinal than in the transverse direction, and fragile. This delicate membrane is not possessed of vessels carrying red blood in the healthy state, but it is penetrated by minute red vessels when inflamed. It lines, with scarcely any perceptible modification, the canals of all the vessels conveying red blood, and the cavities of the heart.

3. The arterial vessels thus formed are surrounded by a sheath of loose cellular tissue, more or less abundant in some parts than in others, permitting the vessels to accommodate themselves to their varying state of dilatation, constriction, &c., and transmitting the vessels which are employed in their nutrition. The elastic properties of the proper coat of the vessels, serve also to accommodate their capacity to the state of the circulating fluid; and as it is generally supposed that they are in a certain degree of distension during life, owing to the quantity of blood constantly being impelled through them by the heart's contractions, so it is believed that the contractions which they display on the removal of this fluid is at least partly owing to the abstraction of the distending cause.

4. No trace of longitudinal fibres can be detected in arteries. The elastic properties which they present in the direction of their axis, when extended beyond their natural limits, and their retraction upon their division, are chiefly owing to the dense cellular coat immediately surrounding the proper fibrous structure of the vessel. The different degrees of tenacity presented by the various structures composing the parietes of these

vessels, acting conjointly with the elasticity of the proper coat, have been considered by many as sufficient to account for the absence of hæmorrhage after laceration of these vessels. Doubtless these circumstances contribute, but I conceive that they are insufficient of themselves to account for this and other phenomena, which will be noticed in the sequel.

5. The arteries are surrounded by the ganglial nerves, which form a reticulum around them; and from this reticulum very minute fibrillæ are given off, and dip into their fibrous tunic. This disposition of the ganglial nerves on the arteries ought to be kept in recollection when we inquire into the functions and diseases of the latter. How far it is necessary, not only to the discharge of the most manifest actions which the arterial system performs, but also to those changes which the blood undergoes in disease, and to the assimilation of the chyle, and other absorbed fluids, I have ventured to state in the article on the Pathology of the BLOOD. It is evidently to the very intimate connection of this class of nerves with the arteries, and the effects resulting therefrom, that we must impute those changes, whether functional or organic, which take place in the latter, and which influence the state of the blood, and the circulation through them. (See the AUTHOR'S Appendix to RICHERAND'S Physiology, p. 556. 613.)

6. II. NERVOUS AFFECTIONS OF ARTERIES.—CLASSIF.:—II. CLASS, I. ORDER (Author).

7. There is sometimes disorder referrible to a particular artery, or arteries, evidently depending on an affection of the nerves supplying them. Of this description are, 1st, Neuralgia of the arteries; 2d, The violent pulsations sometimes felt in a large arterial trunk. 1st. LAENNEC admitted the existence of *neuralgia* of arteries, and considered it to be characterised by acute pain in their course, with increase of their pulsations and the bellows sound; and to be independent of inflammation, as shown by the sudden accession and remission of the symptoms, and their periodic recurrence. That this affection is sometimes connected with irritation, or with an inflammatory state of its nutritious vessels, may or may not be the case; but it is certainly not always so connected.

8. 2d. *Violent pulsation* of arteries is more commonly observed unaccompanied with excessive pain. In these cases a loud bellows sound is often heard in all the principal arteries, particularly those in which the increased pulsation is felt. This affection generally supervenes and disappears suddenly in nervous and debilitated persons, particularly after large losses of blood. Morbid anatomy has not as yet thrown any light on its nature; and therefore we can only refer it to some peculiar influence exerted by the nerves supplying the vessels thus affected, and probably depending originally upon the state of the vital energies of the frame. It is sometimes associated with hypertrophy of the heart. In this case, it is in a great measure to be imputed to that disease.

9. *Treatment of these affections.*—When neuralgic pain is felt in the course of arteries, and is quite unaccompanied by inflammation, the same treatment which is recommended in the article on the *painful affections* of NERVES may be adopted. After morbid secretions and intestinal colluvies have been carried off by purgatives,

tonics combined with antispasmodics may be employed. The preparations of iron, the sulphate of quinine, ammonia, camphor, alone or combined with opium, colchicum, belladonna, or hydrocyanic acid; the external application of the acetate or muriate of morphine, or the cyanuret of potassium, &c. may be tried. In the cases of inordinate pulsations, unassociated with pain of the arteries, attention to the alvine secretions and excretions, and the use of tonics and antispasmodics, will generally be productive of advantage. As these functional disorders are generally consequent upon disturbance of some internal organ or part, sometimes a distant or remote effect of pre-existing disorder, the seat and nature of such disturbance should be investigated, and the treatment directed accordingly. In all such cases, residence in a dry and salubrious air, occasional change of air, gentle and regular exercise, and a light and nutritious diet, will be of much service. (See art. AORTA, §§ 2—6.)

10. III. INFLAMMATION OF ARTERIES.—SYN. *Arteritis*, or *Arteriitis*; *Arterietis*, Hildenbrand. *L'Artérite*, Fr. *Pulsader*—, *Arteri*—, *Schlagaderentzündung*, Ger.

CLASSIF. III. CLASS, I. ORDER (Author, see Preface).

11. DEFIN.—*Great and tumultuous vascular excitement, palpitations, anxiety, sense of heat and throbbing in the course of the principal arteries, followed by collapse of the vital energies, and occasionally by gangrene of a limb.*

12. This disease was not entirely unknown to the ancients, as ARETEUS makes mention of inflammation of the aorta. But notwithstanding the incidental notice which was taken of inflammation of arteries by MORGAGNI, and BOERHAAVE, and afterwards by GRANT, the attention of the medical practitioner was never directed to the subject, until J. P. FRANK noticed it in a particular manner. It is, therefore, to the last-named author that we are chiefly indebted for the numerous researches of pathologists respecting it in modern times. Since the appearance of FRANK'S work, arteritis has received due notice from TESTA, KREYSIG, REIL, BAILLIE, BURNS, CORVISART, SCHMUCK, PORTAL, SCARPA, HODGSON, TRAVERS, RIBES, LAENNEC, BRESCHET, DALBANT, VAJDY, BERTIN, BOULLAUD, GUTHRIE, TROUSSEAU, and several others, and it is now generally recognised as a specific and most important disease, sometimes occurring primarily, occasionally consecutively and conjoined with other diseases, by no means of rare occurrence, and, in whatever form it presents itself, always threatening the most serious consequences.

13. i. PATHOLOGY OF ARTERITIS.—Arteries, being composed of distinct tissues, may be supposed to be liable to all those kinds of inflammatory action, to which each of their constituent parts are most disposed. However frequently inflammatory action may originate in one rather than in more of the coats of an artery, it seems seldom to continue thus limited, but soon affects the rest to a greater or less extent. It may even seize simultaneously upon all the coats; but this is, I think, of comparatively rare occurrence. The individual tissues of an artery most frequently inflamed, in a primary manner, are the internal membrane of the vessel, and its connecting cellular tissue.

14. Arteritis may be *partial* or *general*, as respects its extension through this class of vessels; and it may present every grade of activity, from the most acute to the most chronic form. It generally attacks one or more of the arterial trunks and larger branches. When it affects the arterial capillaries, it constitutes, in the opinion of some pathologists, inflammation itself; but whether it can be demonstrated as existing in this latter class of vessels, or in what respects it may either differ or agree with inflammation when it does thus exist, are points which have not been yet settled by the few pathologists who have agitated the question.

15. Inflammation may possibly, however, seize upon a number of arterial ramifications in an organ, especially in an unhealthy habit of body, or in a part injured by external violence or excessive cold; but when it is thus seated, all circulation through the part is quickly interrupted, owing to the effusion which takes place and destroys the permeability of the vessels. The consequences in such cases are, 1st, sphacelus and gangrene of an extremity or part, as we observe in cases of frost-bite; and 2d, when the inflammation is limited to the capillaries of a circumscribed portion of an organ, particularly when this portion is surrounded by healthy structure, a breaking down of the texture, and its conversion into a foetid purulent-like matter, as in gangrene of the lungs, and some kinds of abscess formed in the parenchyma of several organs.

16. In constitutions possessing the power to limit the inflammation, which has thus seized upon a congeries of arterial vessels, by throwing out coagulable lymph, the extension of the inflammatory process to the larger branches and trunks is prevented; and, if the part already affected be an extremity, a distinct line of separation is thus drawn, or if it be situated in the centre of an organ, a cyst is thus formed by the lymph effused, tending both to the limitation of the inflammation, and to exclude, as it were, the parts which the loss of circulation has deprived of vitality, from the surrounding living textures, and from the contamination which the defect of this natural partition would allow to take place.

17. When the constitutional powers and vital energy of the vessels of the part are insufficient for the formation of the means of limitation here pointed out, the inflammatory action of the smaller arterial vessels extends itself to the larger trunks; and the affection of these, in addition to the pre-existing inflammation of the small branches, increases the mischief; the gangrene extending itself without any line of separation being formed. In this case the constitutional powers fail rapidly, owing to the contamination of the surrounding structures and circulating fluid, from the absorption of the products of inflammation through the venous capillaries of the part, which seldom escape participating in the disease.

18. Such seem to be the results of inflammation affecting a congeries of arterial vessels, or the arterial branches and their ramifications throughout an extremity; and I conceive that those inflammations which are rapidly followed by sphacelation and gangrene, as well as some lesions considered under different heads, and which have been generally referred to the common seat and consequences of inflammation, are of the nature

now described. It seems extremely probable that several lesions of a disorganised and disorganising description, following rapidly upon the first development of deranged circulation, arise from the source now contended for; or, in other words, that some of the consequences usually referred to common inflammation, in conjunction with peculiarity of habit and of the part affected, actually spring from inflammation and obstruction of the arterial vessels, and cannot be otherwise satisfactorily explained.

19. Inflammation of arteries, like inflammations of all other parts, may, however, give rise to effects which will vary according to the degree of intensity of the morbid action, the coat or coats of the vessel in which it originates, or to which it extends, and the habit, diathesis, and constitutional energy of the patient. The duration of this disease, as well as its constitutional effects, will also depend upon the above circumstances; and in inflammation of this part of the system, more perhaps than in the inflammation of any other part of the body, excepting merely the rest of the circulating organs, the primary effects and products of the inflammatory act will be rapidly productive of ulterior effects, serious in their nature and results, even after the morbid action which originated them had altogether disappeared, and could be recognised only in those remoter but palpable consequences, some of which have been alluded to in the preceding paragraphs, and which will be more fully referred to in the sequel, particularly in the section on the morbid structure of arteries (§ 38.).

20. ii. CAUSES. — 1st, The *predisposing causes* of arteritis are generally those of inflammation in general; but those which seem especially to favour the production of this disease, are the gouty and rheumatic diathesis; the middle and advanced epochs of life; certain constitutions of the atmosphere, or epidemic influence; peculiarity of climate, and whatever occasions a diminution of the crasis of the blood, or imparts to it an exciting influence on the vessels; indulgence in the use of much animal food, and vinous and spirituous liquors; a plethoric habit of body, particularly when conjoined to the sanguine and irritable temperaments; prolonged high temperature; intemperate and luxurious habits; the constitutional effects of syphilis or mercury; the suppression of accustomed discharges, particularly the sanguineous; reiterated or prolonged attacks of nervous, convulsive, or spasmodic diseases; and deficient secreting powers of the various emunctories, as the kidneys, liver, &c.

21. 2d, The *exciting causes* of this disease, besides those which are more commonly productive of inflammation, are congelation of parts from great cold, and the sudden exposure to a higher temperature; insolation; punctured, incised, lacerated or contused wounds; surgical operations; ligatures of arteries after the operation of aneurism (CLINE, ABERNETHY, &c.), or amputation, and from tying the umbilical chord (OEMME); excessive suffering from long-continued operations; continued and fatiguing exertions; sudden and violent muscular action; the sudden extension of a part occasioning the elongation of the vessel and rupture of its internal coat; pressure in the course of arterial vessels; violent fits of passion; great mental emotions; exhaustion of the vital powers; pur-

lent and morbid secretions; animal matters and poisons absorbed into the circulation; chemical agents of any description introduced into the vascular system; and the sudden repulsion or suppression of exanthematous fevers and eruptive diseases. PORTAL records an instance of the disease which was occasioned by the repulsion of the eruption of measles. I met with an instance of inflammation of the internal membrane of the heart and arteries, in a fatal case of malignant scarlatina, with an imperfect and evanescent eruption on the skin. M. BRESCHET details several cases in which the disease was consequent upon erysipelas and chronic abscesses. I have found the internal surface both of the arteries and of the veins dark red, and softened, in two fatal cases of puerperal fever, characterised by evident signs of absorption of sanious matter from the uterus. A case also lately came before me of erysipelas followed by gangrenous escars on the sacrum, where the internal surface of the sanguiferous system, and particularly of the aorta and large arteries, as far as they were examined, presented a similar appearance. In all these cases the inspection had been made within eighteen hours after death.

22. The causes of arteritis consist, therefore, 1st, of those which act externally as respects the vessels; and, 2d, of those which irritate in a direct manner the internal surface of the arteries themselves, by being conveyed into the circulating fluid, the properties of which they may have previously changed. But, in whichever of those ways they may act, their first effect seems to be to change or influence the vital energies of the organic nerves ramified to the coats of this system of vessels.

23. 3d, *Anatomical characters*.—As to the particular tissue of the arteries, in which the inflammation originates, I am of opinion that a careful examination of the phenomena of the disease in connection with its causes and complications will warrant the inference, that, when it arises from those causes which act exteriorly to the vessels (§ 21.), and which are chiefly local in their operation, the inflammation is generally limited as to its extent, being confined to a part only of the arterial system, or to two or more considerable branches; that it often affects more than one of the coats of the vessel in this case; and that it generally assumes the sthenic characters, giving rise to those changes which usually result from this form of inflammatory action, such as the effusion of coagulable lymph, forming fibrinous concretions and false membranes in the interior of the vessel, obstructing or obliterating its cavity; red vascular injection, thickening and softening of its tunics; and suppuration, with or without ulceration of its internal membrane.

24. On the other hand, when the disease originates from causes existing within the vessels, and acting through the medium of the blood itself, and more especially when it is complicated with malignant and eruptive fevers, with erysipelas, &c., or is caused by the absorption of morbid secretions, &c. into the current of the circulation, the vascular excitement is rapidly followed by symptoms of an ataxic or asthenic character; the inflammation is chiefly confined to the internal surface of the vessels, but it extends more or less throughout the whole arterial system, and, in

many cases, also to the inner lining of the cavities of the heart, and even of the veins. In cases of this description, the lesions of the arteries which it occasions consist chiefly of a dark red or violet-coloured injection of the inner membrane and connecting cellular tissue; great softening and friability of those tissues, with slight sanious infiltration of the walls of the vessel in different parts.

25. It should not, however, be overlooked, that the inflammation of an artery may frequently commence from local causes, and originate in, and be for a time confined to, a particular trunk or its branches, presenting all the signs of the sthenic form of inflammatory action, and yet, owing to causes lowering the vital energies of the frame, or to the absorption of the matters secreted from the inflamed vessel into the current of the circulation, or to both, may pass into the generally diffused and ataxic state of the disease.

26. iii. SYMPTOMS OF ACUTE ARTERITIS.—These will necessarily vary according to the stage of the disease, the severity and activity of the attack, and the organic changes which the inflammatory action has occasioned in the affected vessels. I shall therefore adduce, *first*, those symptoms which characterise the disease previous to the supervention of those changes which affect this system so as materially to impede its functions, or to change the condition of the circulating fluid; and *next*, those signs which indicate important changes in the state of the vessel, and of the blood itself.

27. The *first stage* is one frequently of much obscurity; and when the inflammation is limited to the vessels of a single limb or organ, it is very difficult to distinguish it from the common inflammation of the part. While the internal tunics of the vessels are yet the chief parts affected, and the effusion of lymph into their interior has either not supervened, or not obstructed their canals, the patient generally feels, either after a rigor, or at first alternating with rigors, an increase of the pulsations of the vessels of the part, with a sensation of heat, uneasiness, or pain. When arteritis is more general, and particularly if it be connected with inflammation of the heart's internal surface, as occasionally occurs, the symptoms are those of fever of an extremely inflammatory type, as has been remarked by J. P. FRANK (*De Cur. Hom. Morb. t. ii. p. 175.*) and M. BOUILLAUD (*Traité Clin. et Exp. de Fièvres. p. 175.*); commencing in rigors, at first alternating with, and followed by, great anxiety, irritability, restlessness, uneasiness, a sensation of burning heat and remarkable pulsation, with increased sensibility in the course of the large arteries. The patient complains of general and unremitting throbbing throughout the system, sometimes felt more intensely in one part than in another. The surface of the body is hot, tumid, and injected; the tongue red, the papillæ erect, and its base furred and loaded; the bowels are costive; thirst is urgent and unquenchable; the urine scanty, voided with a sense of scalding, and high-coloured; the patient is distressed with palpitations. The pulse at this stage of the disease is strong, tumultuous, throbbing, full, and frequent; and the contractions of the heart hurried and tumultuous. To these are sometimes added cough, occurring in paroxysms, with fits of dyspnoea. When the inflammation extends to the aorta and internal

lining of the heart's cavities, the characteristic symptoms of inflammation of those parts (see AORTITIS, &c.) are superadded to the above.

28. The second stage is chiefly characterised by the greater severity of the symptoms, indicating that serious changes are advancing in the internal coats of the vessels, and influencing not only the state of the vital energies of the sanguiferous system, but also the state of the blood. At this period of the disease, the pulse generally becomes extremely frequent, and often wiry, weak, and irregular; whilst the palpitations, anxiety, and paroxysms of dyspnoea increase. The tongue is either dry, the papillæ erect, and its centre furred with a dark mucus or sordes; or it is smooth, glossy, and of a dark tint. The patient is liable to startings and spasms in different parts of the body. The desire for drink increases; the strength sinks; the countenance at first shrinks, is pallid or haggard, but, towards an unfavourable close of this stage, it often becomes somewhat bloated, œdematous, or cadaverous, occasionally injected, and the lips purplish. The extremities are frequently œdematous; and they, as well as other parts of the body, are sometimes affected with wheals, ecchymosis, phlyctenæ, or large vesications. In some cases, effusions of sero-albuminous fluids take place in some of the shut cavities; the surface of the body is covered by a cold perspiration; the extremities become cold, and sometimes of a purplish red colour; and a low muttering delirium appears during the night, from which, at last, the patient is never entirely exempt. To these often supervene a tendency to syncope upon raising the head; irregular palpitations; weak, irregular, hurried, and quick pulse; and a quick, short, and difficult respiration; sometimes orthopnoea and distressing cough. Hiccup and convulsions at last appear, and the patient expires.

29. If the inflammation be seated in large trunks, the serum effused from the internal surface of the inflamed vessel necessarily comes in contact with the circulating fluid; but I believe it does not readily mix with it in persons of a sound constitution, or whose vital energies have not been materially affected, but forms a coagulum, which either sheaths the internal surface of the vessel, partially obstructing it, or altogether filling up its channel. In this case, the symptoms indicate interruption of the circulation through a considerable branch of an artery: the limb becomes œdematous, cold, leucophlegmatic, or purplish coloured, with irregular phlyctenæ and large vesications on its surface, which sometimes go on to gangrene; especially when the disease has extended to the collateral arteries, which, if they had remained unaffected, would have performed the functions of the inflamed and obstructed trunk.

30. When atheritis occurs in a weak or cachectic habit of body, the fluid secreted from the inflamed internal surface of the vessels, owing to the state of the constitutional powers, will not coagulate, but, being of a dissolved and sanious quality, readily mixes with the blood, and no interruption to the circulation through the inflamed vessels occurs; but the energies of life become depressed from the morbid state of the vital current thus occasioned, and many of the symptoms of ataxic or malignant fever manifest themselves; — such

as great prostration of the powers of the frame; low delirium; an impeded and morbid state of the secretions and excretions; weak, quick, and irregular pulse; a cadaverous and lurid countenance; accumulations of dark mucous sordes about the tongue and mouth; flaccidity of the soft solids, with the rest of the phenomena described as consequent upon *Inflammation of VEINS*.

31. iv. CHRONIC ARTERITIS. — The more acute and active states of arteritis, although frequently admitting only of a doubtful recognition during the life of the patient, are more readily ascertained than the chronic forms of the disease. These latter, however, seem more frequently limited to particular arteries than the acute, and hence oftener produce local effects; but these are generally so slight, and of so equivocal a character, that they commonly escape detection, and are unattended to by the patient until the lesion on which they depend arrives at that degree of advancement which seriously disturbs the functions, and even the vitality, of the part. A very large proportion of the lesions which will be described hereafter (§ 38.) seem to originate in chronic states of inflammation; and, if not actually commencing in these states, they are frequently complicated with them. It will be unnecessary further to notice those symptoms which seem to indicate the presence of chronic arteritis, than to state that they consist of many of the signs already adduced as attendant on the acute forms of the disease, but in a much slighter degree; and frequently no functional lesion can be remarked. When, however, the circulation through the vessel becomes impeded or obstructed, we may infer chronic disease of the arteries from the inequality or entire absence of the pulsation in these arteries supplying the part whose functions are most affected; from œdema, coldness, discolouration, vesications, or from signs of the *grangræna senilis* in a limb; or from a feeling of weakness, and a state approaching to paralysis of an extremity or part.

32. v. COMPLICATIONS. — The states of morbid association of which arteritis forms an especial part have been more frequently disclosed to us after death than recognised during life; nor is it to be expected that, in some of the associations in which it has presented itself, it can be ascertained by the most diligent investigation of the case previous to dissolution. We are still so much in want of faithfully observed cases of the disease, even in its simple and unmasked forms, and of correct information on various topics respecting its history and pathology, as to render our diagnosis imperfect and doubtful; and how much more difficult must be our attempts to recognise it in its complicated forms, when it is masked by other diseases, the phenomena of which obscure it from the observation of the practitioner, and even abstract the attention of the patient himself from the feelings it may awaken. In noticing, therefore, the complications of which this disease often forms a part, it is with the sole view of turning attention to their importance, and in order that the circumstance may receive due consideration, when we give our prognosis respecting those maladies with which it has been found associated, and when we devise means for either their relief or their removal.

33. Inflammation of the arteries has been observed in fatal cases of inflammatory and malignant

fevers, and in those which have been characterised by great vascular excitement at their commencement, with symptoms of ataxy during their progress. In the great majority of such cases, it is a consecutive affection occasioned either by a greater concentration of the morbid action in a particular system, as explained when treating of fevers; or by an alteration of the properties of the blood, owing to hurtful materials having accumulated in it from deficient action of the eliminating organs, or to a morbid state of the nervous influence imparted to the blood from the vessels in which it circulates. (See BLOOD.)

34. Owing to similar causes, *arteritis* is sometimes consecutive of *eruptive fevers*, particularly when the eruption, and the morbid evacuation of which it consists, are imperfectly developed or prematurely suppressed; or it may supervene to *small-pox*, occasioning the most dangerous part of the symptoms forming the secondary fever of this disease. In cases of this description, the *arteritis* is almost always general, chiefly limited to the serous membrane of the arteries, but extending also to the same membrane of the veins; and evidently induced by the altered state of the blood, and the presence in it of hurtful materials. To this cause chiefly is to be imputed its occasional occurrence during *erysipelas*, *phlebitis*, and as one of the chief lesions observed in fatal cases of those diseases to which the term *puerperal fevers* has been applied. The complication of *arteritis* with *phlebitis* is one of the most frequent which occurs. That this should be the case, we might infer from the circumstance of the same causes generally acting upon both divisions of the vascular system, particularly those which act through the medium of the circulating fluid. M. BRÉSCHET found inflammation of the internal surface of the veins in a very large proportion of the cases (8 in 13) of *arteritis* which he has detailed at length in his interesting memoir.

35. *Arteritis* has likewise been found associated with *inflammation of the heart*, with that of the *lungs*, and with *tetanus*, particularly traumatic tetanus. A case of this last complication is alluded to by the writer of an able article in the second volume of the *Medico-Chirurgical Review*. It has also been observed, although rarely, conjoined with serous effusion into the shut cavities, particularly the pericardium, pleura, and peritoneum.

36. vi. **DIAGNOSIS.** — It has been very justly remarked by the writer to whom I have already referred, that, until numerous and diversified observations in clinical practice, illustrated by the examination of fatal cases, shall have further enlarged our knowledge of this malady, any attempt to delineate the symptoms which are diagnostic of its presence must necessarily be somewhat imperfect. But it may generally be inferred, — when the principal symptoms which have been enumerated appear — when the heat and pain attendant on this, as on other inflammations, are not concentrated in one part or organ, but are more or less generally diffused, particularly in the course of the arterial vessels — when these sensations are accompanied with an audible or perceptible impetuosity of action, propagated from the large trunks to the smaller and more superficial ramifications — and when, moreover, anasarctous injection of the surface or of the limbs, followed by wheals, vesications, or ecchymosed

patches, supervene, — that the disease is inflammation of the arterial system, either in its partial or general form.

37. vii. The **PROGNOSIS** of *arteritis* may be said to be, upon the whole, unfavourable, even as respects its more immediate effects, in the acute states of the disease; but chiefly as regards its remote consequences in its chronic forms. The prognosis is more unfavourable when it is complicated with, or supervenes on, other diseases (§§ 33—35.): The morbid changes which it usually occasions are fully described in the next section of this article.

Before proceeding to offer any observations on the *treatment* of *arteritis*, I will describe the various changes of structures which arteries present, as the greatest proportion of these changes are produced by inflammatory action in some one of its various grades or states.

38. IV. **MORBID STRUCTURE OF ARTERIES.** — 1st, *Lesions of the individual coats of arteries.* — A. *Redness of the INNER MEMBRANE of arteries* is often observed in post mortem examinations. — a. It seems to proceed from three causes; 1st, from the imbibition of the colouring particles of the blood remaining in the vessels, being entirely the consequence of death, and the result of incipient decomposition; 2d, from a change in the state of the blood occurring in the course of the disease which occasioned death, and existing some time before this event; and, 3rd, from a morbid or *injected* state of the capillaries ramified in the coats of the vessel, or terminating in this membrane. In an epidemic amongst horses, which occurred at Paris in 1825, characterised by symptoms of disease of the thoracic viscera, no morbid appearances were found in the lungs, but the internal membrane of the large vessels was uniformly red, and the muscular structure of the heart remarkably softened. From the experiments of GENDRIN (*Hist. Anat. des Inflamm.* t. ii. p. 9.), it is evident that the same varieties of colour, which we occasionally observe in arteries after death, may be produced by artificial irritation. There is, however, this important difference, — that when their redness is produced artificially, it is accompanied by other alterations of tissue, such as softening, serous or purulent infiltration, &c.; whereas, in almost all the cases where the arteries have been found of a red colour throughout, the change was unattended by any other morbid appearance in them. I believe that this colouration of the internal membrane of the arteries, as well as of the cavities of the heart, is more frequently owing to a morbid condition of the blood itself, than to any inflammatory change in them. This opinion is confirmed by the circumstances and states of disease in which it commonly occurs; these chiefly consisting of depressed vital energies, deficient secretory power, and a consequent morbid condition of the blood itself.

39. b. The internal membrane of arteries sometimes loses its *tenuity* and natural *transparency*, either in a few isolated points merely, or through a great extent of its surface. This state may amount to considerable *thickening* and *opacity*; but in many cases these appearances do not depend upon any remarkable change in this membrane, but upon an albuminous exudation in its connecting cellular tissue.

40. *c.* Softening also takes place in this membrane, which is sometimes so friable as to be reduced to a pulpy mass by the slightest scraping with the scalpel. Possibly, owing to this state of the inner membrane, its laceration may take place upon stretching the vessel by the more violent motions of the body, or of a limb.

41. *d.* Rupture or laceration of the internal coat of an artery is sometimes met with: it necessarily occasions an effusion of lymph from the lacerated part, and the projection of the flaps of the divided coat into the canal of the vessel, either partially or entirely obstructing it. To this occurrence is chiefly to be imputed the cases of spontaneous obstruction of arteries, which are sometimes met with. This subject has been well illustrated by Mr. TURNER, in the third volume of the Transactions of the Medico-Chirurgical Society of Edinburgh.

42. *e.* Ulceration of the internal membrane of arteries is not infrequent. The ulcers are generally round; occasionally one only is to be found. Sometimes the large arterial trunks, and particularly the aorta, are studded with them. But this is rarely observed, unless other alterations exist in the subjacent tissues, such as ossification, softening, &c. M. BOULLAUD is of opinion that the ulceration of the inner coat occasionally admits of cicatrisation.

43. *B.* The MIDDLE COAT is more frequently diseased than the internal. It is often soft and friable, and deprived of its natural elasticity; giving rise to serious modifications of the functions of the circulating system. M. ANDRAL has found this coat remarkably hypertrophied; the yellow fibrous tissue of which it is composed being as evident in the human subject as it is in the horse. This change may be confined to particular parts, occasioning irregularities in the diameters of the arterial canals, or it may extend throughout a whole artery. The fibrous coat may also become atrophied. In this state it approaches to the appearance of cellular tissue, and is much thinner, resembling the tunic of veins; and the artery loses its elasticity and collapses when divided. This coat may also require much rigidity, and be transformed into cartilaginous or even osseous rings, embracing the whole circumference of the vessel. This change is rarely met with in the aorta, but it not infrequently occurs in large arterial trunks, as the femoral artery, &c. Ulceration may extend to and penetrate this coat, most frequently advancing from the internal membrane, and be followed by dilatation or rupture of the external tunic (§ 47. *et seq.*)

44. *C.* The EXTERNAL OR CELLULAR COAT of arteries is liable to fewer alterations than the other coats; it often remains sound when they are extensively diseased, when it has alone to sustain the column of blood injected through it. But it also frequently participates in the changes of the other coats, becoming ruptured from the pressure of the stream of blood thrown into it, and more rarely ulcerated. — The foregoing changes of the individual coats of an artery combine to affect its functions and condition, and give rise to important alterations of its structure and of its calibre, which may be increased, diminished, or entirely obliterated. Each of these requires a separate but brief consideration.

45. 2d, *Changes of the structure and calibre of arteries.* — *A. ANEURISM.* — *a. True aneurism,*

or dilatation of arteries occurs — 1st, in a part only of its circumference, and, 2d, in its entire circumference: the latter is the more frequent occurrence of the two: it may embrace but a small extent of the vessel, or it may extend to a considerable portion; as, for instance, to nearly the whole of the aorta. Dilatation of a part only of the circumference of an artery is rare, but certainly not so rare as to warrant some authors in disputing its existence. M. ANDRAL states, that on more occasions than one he has traced distinctly the three arterial coats passing over the walls of a sac which seemed as if appended to the artery, with the cavity of which it communicated. Dilatation either of a part, or the whole, of the circumference of an artery, constitutes the true aneurism of authors; and according to its extent it may constitute simple dilatation, or true aneurism in its first stage, and sacculated aneurism, or the advanced state of this disease.

46. The coats of a dilated portion of artery, although not ruptured, may be otherwise altered. They are frequently thinner than natural, and the middle coat is generally deprived of its elasticity. In this state the vessel yields like a vein to the distending impetus of the blood. In other cases, the coats of the dilated portion of artery are hypertrophied. M. ANDRAL likens this state to the dilatations of the stomach and heart, which are often accompanied with an increased thickness of their parietes.

47. *b. False aneurism.* — *Mixed aneurism.* — *Dilatation with rupture of one or more of the coats, constituting the false aneurism of authors, is another frequent alteration.* The internal and middle coats are those most frequently ruptured, the blood coming in contact with the external or cellular coat or sheath, dilating it in the form of a pouch, and thus forming the aneurismal sac. The parietes of this sac are generally much thicker than the cellular sheath of the vessel was originally, owing to the gradual condensation of the surrounding cellular tissue from the pressure of the tumour, and the additional envelope it thus acquires. The interior of the sac is filled more or less with fibrous coagula, arranged in concentric layers, the more exterior of which frequently become so dense as to be distinguished with difficulty from the parietes of the sac. Around the exterior of the sac a degree of irritation is induced, giving rise to adhesions, which unite it more or less firmly to the surrounding parts. But these parts suffer other changes, particularly as the aneurismal tumour increases: they are mechanically compressed or displaced; or they are worn away by absorption promoted by its pulsations, or by inflammatory irritation terminating in ulceration and destruction of parts. This effect upon the adjoining structures has been shown under the article ANEURISM OF THE AORTA, and it is therefore unnecessary to illustrate it further. According to some authors, false aneurism consists of the ulceration or perforation of the internal coats, and of the dilatation of the external tunic only; the changes above described constituting mixed aneurism.

48. *c. Diffused aneurism, &c.* — In general the irritation created around the sac attacks, after a time, the sac itself, occasioning its ulceration and perforation. Hæmorrhage is then the result, which may be so great as at once to occasion death. It is frequently arrested by the anat-

mical relations of the part: as when blood flows into the pericardium; or when the blood passes into the parenchyma, or loose cellular tissue connecting different organs or structures; in which case it passes into the state of *diffused aneurism*. In some cases the hæmorrhage is arrested by adhesions formed around the sac, constituting a second envelope to it, which confines the blood, and prevents it for a time from being further effused. Perforation of the sac, however, may take place without hæmorrhage, or even the production of *diffused aneurism*. This happens when a part in contact with the sac supplies the place of that portion of its parietes which has been destroyed, and affords sufficient resistance to the escape of the blood. Thus we have seen that the blood, in aneurism of the AORTA, may actually wash the partially destroyed vertebræ, no effusion taking place till still further destruction is occasioned; and the tumour, in other cases, coming in contact with the periosteum, produces thickening of this structure, or the secretion of an osseous matter from it which partially surrounds the sac, forming an envelope to it, and preventing the escape of its contents, until this also is destroyed.

49. In *false* and *mixed aneurisms*, the inner and middle coats are first perforated or ruptured, and the *third* coat either remains entire, or gives way at some remote period, and thus a *secondary diffused aneurism* is formed (§ 48.). But there is another form of *diffused aneurism*, in which all the coats of the vessel are ruptured or perforated at once, and the blood, passing entirely out of the vessel, forms no sac, but is diffused in the adjoining parts; or it impacts the cellular and parenchymatous structure in its vicinity into a species of sac or envelope; or it is poured out into a shut cavity, or into some organ, whence it may be discharged externally, thus constituting *primary diffused aneurism*. In the majority of cases, however, the aperture in the artery is the result of ulceration of one or more of the coats of the vessel, the remaining tunica giving way before the impetus of the circulation; the blood being either confined by the surrounding parts, or escaping into a cavity, according to the situation of the artery, and of the aperture in it. This perforation and rupture of all the coats occur chiefly in the arteries of internal viscera, as in the splenic, hepatic, emulgent, iliac, &c. In a case recorded by Mr. GUNN (*Edin. Med. and Surg. Journ.* vol. xxxi. p. 90.), these changes took place in the pulmonary artery.

50. Aneurisms may terminate favourably, a spontaneous cure being sometimes effected by some one of the following processes:—1st, by a gradual contraction of the sac, and absorption of the coagula; 2d, by the compression exerted by the sac upon the part of the artery immediately above it; 3d, by gangrene of the sac and obliteration of the artery; 4th, by inflammation or abscesses in the vicinity, and the coagulable lymph thrown out, obliterating the artery, as in the preceding case; and 5th, by inflammation of the sac extending to the artery, and giving rise to adhesive inflammation of its interior, and ultimately to its obliteration.

51. B. NARROWING of arteries is either congenital or the effect of disease: when the latter, it is very frequently associated with, or occasioned by, ossific deposits,—a change which will be considered in the sequel. It is chiefly in the aorta and

large vessels departing from it that we meet with either congenital or morbid narrowing. *Congenital* contraction of the aorta is generally connected with extreme thinness of its parietes; and in some cases this defective development has been so remarkable that the abdominal aorta has not equalled the usual size of the external iliac artery.

52. The contraction of the aorta, or of an arterial branch, may exist throughout its extent, or may be confined to a particular part. The abdominal portion of the aorta is more frequently contracted (see AORTA) than the thoracic; and when the former is narrowed, the latter is often dilated. Sometimes, however, the artery retains its natural calibre both above and below the constricted part: instances of this have been recorded by M. PARIS, in the second volume of DESAULT'S *Journal*, and by M. REYNAUD (*Journ. Hebd. de Méd.* t. i. p. 161.). In many cases of constriction such as I have now noticed, it is difficult to determine whether this change has been congenital or the result of disease, inasmuch as the coats of the vessel have appeared unaltered from the healthy state. But there can be no difficulty in determining in favour of the latter alternative, when the coats of the contracted portion are thickened, or contain ossific deposits, or are otherwise changed. When the contraction is the result of disease, it is sometimes very remarkable, the canal of the vessel being nearly obliterated. The narrowing found in the principal trunks or branches of arteries is almost always the result of inflammatory disease; most commonly of ossific deposits, or of chronic inflammation.

53. C. OBLITERATION of arteries is frequently observed. This lesion may occur in any part of the system, even in the aorta itself, but it is most commonly met with in the second or third order of arteries. The smaller branches may also be obliterated; but they less frequently become the objects of examination than the larger trunks. The canal of an artery may be obliterated, 1st, by fibrous coagula adhering firmly to the parietes of the vessel, or incorporated with them; 2d, by the conversion of the vessel to a ligamentous chord; 3d, by osseous concretions, or other morbid growths, filling entirely its cavity; and, 4th, by the advanced progress of aneurism to a spontaneous cure.

54. a. The first species of obliteration has been found in the aorta by Professor MONRO (*Edin. Journ. of Med. Science*, vol. ii. p. 351.); the part affected being somewhat contracted and filled up by a plug of fibrine, which adhered to the surface of the vessel by coagulable lymph. This form of disease is common in the arteries of the extremities, particularly the lower, and is sometimes owing to the rupture of the internal coat of the vessel. It occurs also in cases of *gangræna senilis*, and, with the *third* species (§ 56.), is a frequent cause of the gangrene. It seems most probable that it is a more immediate consequence of inflammation than the *second* species.

55. b. The second form of obliteration is not uncommon in large branches of arteries, and has been found, in two cases, in the aorta: it is evidently a more remote cause of inflammation than the foregoing. The circulation being entirely obstructed, by the coagulable or fibrous lymph poured out by the inflamed or ruptured internal membrane, and by the coagula thus formed, and

being kept up by the enlargement of collateral branches, the obstructed part is deprived of its functions, and subsequently undergoes those changes which all vascular or other canals experience when they no longer are pervious to the fluids which usually circulate through them,—they have the fibrinous coagula, which have been formed in their cavities, and the lymph effused between their coats, absorbed, and their coats become condensed into ligamentous chords.

56. *c.* The *third* species has been met with in the aorta by Dr. GOODISON (*Dub. Hosp. Rep.* vol. ii. p. 193.), and M. VELPEAU (*Rev. Méd.* 1825, t. iii. p. 326.). In Dr. GOODISON'S case, an osseous deposit surrounded the canal of the vessel, which was completely filled at this part with a dense fleshy and fibrinous mass, resembling the structure of the heart. A similar obliteration also existed in the iliac arteries. In M. VELPEAU'S case, the obliteration was owing to the formation of a scirrhus or carcinomatous tumour in the vessel, resembling similar tumours developed in different parts of the body. Obliteration by polypous or other growths, by fibrinous coagula and coagulable lymph, by ossific deposits, &c. are also found in large arterial branches, especially in those supplying the lower extremities. The obliteration of the arteries by ossification is one of the principal causes of the gangrene of aged persons. When a considerable artery, or even the aorta, becomes either much obstructed, or entirely obliterated, in any of the above ways, the circulation is generally carried on by enlarged collateral vessels.

57. *d.* The *fourth* species has been observed in several large arterial trunks. Dr. MONRO'S case of obliteration of the aorta may be partly ascribed to this cause; the coats of the vessel, although entire, being dilated below the constricted part.

58. *D. ALBUMINOUS AND PURULENT MATTER.*—M. GENDRIN (*Hist. Anat. des Inflamm.* t. ii. p. 9.) has clearly proved, by his experiments, that, when an artery is artificially irritated, its parietes soon become injected, swollen, softened, and infiltrated by a serous fluid; its internal surface is coated by an *albuminous exudation*, and *collections of pus* form, either in the interior of the vessel, or between its coats. He has, moreover, demonstrated that, if the artery continues full of blood during the experiment, this fluid is coagulated, and altered in a variety of ways by the morbid secretion poured into it from the internal surface of the inflamed vessel. Similar appearances have been observed from disease, particularly in the aorta and large arterial trunks, where they are most obvious. Mr. HODGSON and M. BOUVILLAUD found the internal surface of the aorta lined with a perfect *false membrane*; and when this was removed, the surface of the vessel was of a bright red colour. M. ANDRAL has observed the internal membrane of the artery raised by small *abscesses*, sometimes as large as the size of a nut, situated between the internal and middle coats. It is probably to the bursting of those into the vessel that ulceration of the internal tunics is owing. Pus is also sometimes found in the interior of arteries, either unmixed with the blood, or mixed with it and altering its appearance.

59. *E. ATHEROMATOUS* matter is frequently found between the inner and middle coats of arteries. It was first noticed in this situation by

MONRO and HALLER. It is generally of the consistence of suet, of a fatty opaque appearance, is greasy to the touch, with minute gritty particles thinly scattered through it. In some cases it resembles a semi-concrete pus, and seems to result from the changes which pus may have undergone subsequently to its secretion. In other cases the atheromatous matter has a cheesy appearance, or it abounds in gritty particles, which occasionally even exceed the suety or fatty part; and the deposition thus passes into the form of a calcareous concretion. It is extremely probable that these varieties of morbid formation are connected with chronic inflammatory action of the coats of the vessel.

60. A variety of the atheromatous matter has been described by MORGAGNI, SCARPA, STENIZEL, and CRAIGIE, under the denomination of *steatomatous* deposition. The name, however, as Dr. CRAIGIE has remarked, is not well chosen, inasmuch as this formation is not adipose, but a firm cheesy or waxy matter, of a yellowish or fawn colour. It seems merely a more concrete variety of the foregoing, and differing from it chiefly in the absence of gritty particles. It is more frequently found at the bifurcations of arteries, but it is not limited to those situations; and is generally deposited between the inner and middle coats. When the quantity of this matter is considerable, it encroaches on the calibre of the vessel. This substance is met with either alone, or with patches of calcareous deposit. It probably derives its origin from a similar source to the atheromatous matter; and, according to SCARPA, always terminates in ulceration; but this is not invariably the case, as it has been observed, particularly when unattended with calcareous formations, distending the coats of the vessel to a great extent without any ulceration. This change, however, takes place very generally, either when the deposition of this matter is considerable, or when associated with calcareous formations. When ulceration takes place, the coats of the vessel are soon destroyed to a greater or less extent, and rupture follows; taking place, as shown by Mr. HODGSON, in a transverse direction to the axis of the vessel, and giving rise to extensive or fatal hæmorrhage, or to circumscribed or diffused aneurism, according to the situation of the aperture in the vessel.

61. *F. CALCAREOUS or osseous concretions* are the most frequent morbid appearances presented by arteries. These concretions, however, differ from healthy bone chiefly in wanting the fibrous structure, in not being necessarily deposited in a cartilaginous matrix, in consisting of a larger proportion of phosphate of lime, and less animal matter, and in presenting an irregular, homogeneous, and unorganised appearance. BICHAT and BAILLIE considered that the larger proportion of persons above sixty years of age have some part of the arterial system affected by these formations. This change is very seldom observed in early life. YOUNG found it, however, in an infant; WILSON in a young child; and ANDRAL in the aorta of a child of eight years of age. M. ANDRAL has met with ossific laminæ in the aorta, in five or six persons of from eighteen to twenty-four years of age; and an extensive ossification of the superior mesenteric artery of a person not quite thirty. This species of formation always is seated

between the muscular coat and the internal-membrane, which it often detaches from its connections; and it originates either in the atheromatous matter described (§ 59.), the place of which it sometimes takes; or in those whitish patches already noticed, which apparently consist of an albuminous exudation formed between the inner and middle coats, and which pass from the albuminous, first to the cartilaginous state, and subsequently to that of bone.

62. *a.* But this is not the only change which the vessel undergoes, for whilst the calcareous deposits are going forward, the middle coat becomes either hypertrophied, thus contributing to the thickened appearance which the vessel sometimes presents, or atrophied, being apparently replaced by the calcareous concretion, and leading to the mistaken opinion that this coat itself has been transformed into bone. The osseous concretions exist in various forms: sometimes they consist of minute grains; at other times of irregular plates of different sizes; occasionally they incrust the artery and convert it into an inflexible tube; and, more rarely, they give the sensation of a number of small bodies moving on each other, and as if jointed together.

63. The ossific concretions may be very considerable, without in any way changing the calibre or even the form of the vessel; or they may project into it so considerably as to obstruct, or even to obliterate its canal. They thus occasion *gangrena senilis*. It has even been supposed, — and the opinion is very probable, — that they may project through, or penetrate the internal membrane, and fall into the cavity of the vessel; and, being conveyed onwards with the current of blood until they arrive at arteries of smaller calibre, may thus completely obstruct them. The *calcareous concretions* found in some rare instances plugging up the canal of the vessel, evidently are produced in this way.

64. *b.* As to the comparative frequency of this lesion in various arteries, I may add a few remarks, derived from the interesting materials supplied by M. ANDRAL (*Anat. Path. t. ii. p. 395.*). The aorta is the most liable of any to ossification in some part or another; but every one of the branches proceeding from it may likewise be the seat of this change. The coronary arteries are frequently ossified, both in their trunks and in their subdivisions. The large vessels which arise from the arch of the aorta often present at their origin a bony ridge projecting into their interior. The cerebral arteries of old persons are frequently found studded with cartilaginous and osseous laminæ; and M. BOUILLAUD has shown that this change disposes remarkably to apoplexy with sanguineous extravasation. Ossification is very common in the splenic artery, but exceedingly rare in the hepatic, and coronary artery of the stomach. A bony ridge is often found at the origin of the common iliacs. The arteries of the lower extremities are not infrequently the seat of these concretions; and they sometimes occur in the radial artery of aged persons. M. ANDRAL has never met with this alteration in the hypogastric artery. HALLER met with it once in this vessel (*Opusc. Path. Obs. 59.*); and this is the only case of the kind on record. — All the morbid depositions described above have been found in the pulmonary artery, but

much more rarely than in the aorta and vessels proceeding from it.

65. *c. Origin of osseous formations in the arteries.* — The ossification of arteries has been ascribed by many authors to slight chronic inflammatory action. The experiments of M. RAYER and M. CRUVEILHIER seem to confirm this inference, as an occasional occurrence at least, particularly in the fibrous and cartilaginous structures: increased vascular action of those structures, artificially excited, being generally followed by ossiform depositions; but, in a number of cases, particularly in those where the deposit takes place in the cellular tissues, no inflammatory action can be detected previously to this change: besides, increased vascular action frequently exists, without being attended with ossiform depositions. This lesion therefore cannot be altogether ascribed to this cause, although frequently resulting from it, in a certain order of tissues. It would be more correct to consider it merely as a consequence of disorder of the natural process of nutrition and secretion, frequently induced, in particular tissues, by a chronic state of inflammatory action. But to what cause is this disorder of the nutritive function to be imputed, particularly when it occurs in parts which have not evinced any sign of inflammatory action, as in the cellular tissue connecting the internal coats of arteries? The importance of this inquiry may appear from the very great proportion of persons, in advanced years, who are affected, in some organ or tissue, with this lesion, and from the remarkable part it performs in the production of a number of dangerous diseases.

66. In answer to this, M. ANDRAL very plausibly observes, that physicians have frequently noticed the existence or succession of three different forms of calcareous productions in persons of a gouty diathesis: 1st, gravel and urinary calculi; 2d, hard concretions in the small joints; and, 3d, ossiform productions in the arterial system and other parts. Is it not, therefore, probable that morbid ossification proceeds from a similar cause to those other calcareous formations? We have seen that gout generally originates in an excessive use of animal food, conjoined with deficient assimilative and secreting powers of the frame. The highly azotised blood of a person thus circumstanced becomes surcharged with urea and phosphate of lime, as evinced by the state of the urinary secretions, which always, in such cases, abounds with uric acid and the earthy salts. The experiments of M. MAGENDIE have proved that by changing the diet of a person who has been living chiefly upon animal food, and by substituting substances containing no azote, the uric acid and phosphates disappear from the urine. May we not, therefore, infer that in consequence of the excessive use of animal food conjoined with imperfect assimilative and secreting powers, these substances will accumulate in the blood to a hurtful extent; the urinary organs being unable to eliminate them entirely from the circulating fluid? The necessary result of this state of the blood will be, that these substances will occasionally be deposited in other parts, giving origin to the uric acid concretions found in the small joints, and to the phosphate of lime deposits found in the arterial system and some other parts. From this it will be apparent

that the ossific formations met with in the arteries are derived from a similar origin to that which has been more fully explained under the articles GOUT and URINARY CALCULI. The increased vascularity, observed frequently to co-exist with the morbid secretion of calcareous matter, may proceed from the irritation produced in the capillaries by the morbid matters circulating in them; or it may be a necessary attendant upon the secretory process, especially when this process is of a morbid description; or the accidental occurrence of irritation and increased vascular action in the interior coats of the vessel may prove the determining cause of the ossiform deposit, to the formation of which a disposition had previously existed, owing to the excessive abundance of the phosphates in the blood. If this explanation of the origin of ossification in the arteries be correct, a rational method of preventing and combating this lesion is presented to us for adoption.

67. V. TREATMENT.—A. The more acute states of arteritis require the same general principles and details of treatment as inflammations of other parts. General and local depletions, calomel and oleaginous purgatives, cathartic enemata, diaphoretics consisting chiefly of camphor, antimony, and opium, &c. (F. 39. 184. 358. 460.); cooling diluents, and the rest of the antiphlogistic regimen, are indispensably requisite. After a copious depletion, practised so as not to occasion full syncope, the following will be found of service in preventing the re-accession of increased vascular action.

No. 33. R. Camphoræ rasæ gr. iij.—v.; Pulv. Jacobi Veri gr. v. (vel Antimonii Potassio-Tart. gr. ss.); Calomel. gr. xij.; Opii Puri gr. ij.—iij.; Conserv. Rosar. q. s. ut fiat Bolus, statim post venæsectionem capiendus.

68. In the more acute states of arteritis, digitalis and emollient diluents, with nitrate of potash, or the vegetable acids, may be exhibited. After depletions have been carried as far as may be considered prudent, and when there exists no constitutional vice contra-indicating the practice, the mercurial preparations may be given to the extent of affecting the gums. The repetition of the bolus now prescribed will generally be sufficient for this purpose, the bowels having been well evacuated previously. In this form of arteritis, HILDENBRAND recommends (*Instit. Med.* t. iii. p. 26.) cold epithems over the seat of the inflamed vessels, the internal use of lemon ices, and the cautious exhibition of the *superacetate* of lead and opium (F. 206.), after depletions have been practised. *Colechicum* may also be given, or substituted for digitalis; but these medicines require great caution in their exhibition, particularly after large depletions, and when antimonials precede or accompany them. The diet ought to be very low, cooling, and chiefly farinaceous; and, during recovery, the more heating kinds of animal food should be abstained from. During the disease, as well as during convalescence, perfect tranquillity of body and mind should be insisted on.

69. In some states of acute arteritis, it may not be advisable to lower the powers of life too much; as we may thereby risk the occurrence of arterial throbbings, the extension of disease along the internal membrane of the vessel, and the vitiation of the circulating mass by the secretion poured into it from the inflamed surface. The

tendency, also, to limit the inflammation by the formation of coagulable lymph, when the period of resolution is past, may also be overcome by too great depression of the vital energies, which ought therefore to be supported in extreme cases, and not depressed too low in others.

70. B. The more chronic states of arteritis require cooling purgatives, occasional depletions, and a low refrigerant diet and regimen. A vegetable, particularly a farinaceous diet, is extremely serviceable in these states of the disease, chiefly by preventing the consequences to which they usually lead. The richer and more stimulating kinds of animal food, and particularly pork, should be constantly avoided, and all tendency to plethora suppressed or subdued. In the chronic as well as the acute diseases of arteries, physical and moral tranquillity is particularly required. The abdominal secretions and excretions ought to be duly examined and regulated, undue sinking of the vital energies prevented or counteracted, pure air prescribed, and due attention paid to the digestive functions.

71. C. The consequences of inflammation of arteries, whether those more palpable changes which constitute the different kinds of aneurism, or those which are merely matters of more doubtful inference, can be treated only upon the above principles: above all, vascular plethora must be avoided, and tranquillity observed. There is, however, one fact, which, I consider, should not be lost sight of by the practitioner, and which is the result of attentive observation; namely, that, even in aneurism, more mischief will be derived from depressing the vital energies of the frame too low, than from observing a more moderate, or rather a less vigorous, mode of treatment. When carried too far, relatively to the circumstances of the case, those guards which the restorative powers of the frame set up against the extension of the disease are thrown down; the destruction of adjoining parts extends; the fibrous coagula which fortify the weakened parietes of the vessel, and tend even to a spontaneous cure of the disease (§ 50.), assume, as Mr. GUINÉE has very justly remarked, a loose and spongy state, and allow the blood to pass through it, or between it and the coat or coats of the vessel; and the disease, consequently, makes rapid progress. There can be no doubt, as hinted at by this eminent surgeon, that the extension, and ultimately the bursting, of aneurisms, are not altogether owing to the impetus of the blood in the vessel; and that, therefore, the treatment which is solely directed to this point must be deficient. The suggestions now offered (§§ 69, 70.), as well as those stated in the article on ANEURISM OF THE AORTA, will be sufficient to guide the practitioner in this respect.

72. D. The complications of inflammations of arteries, and their consequences (§ 32. et seq.), require attention to the fact, that, when arteritis supervenes in the course of other diseases, it is generally during those stages which are characterised by depression of the constitutional powers, when the circulating fluid becomes materially changed from its healthy condition, and most probably loaded with an unusual quantity of unassimilated, morbid, or irritating materials. Indeed, these are the circumstances which favour the occurrence of all inflammations affecting the different circulating systems — the lymphatic as

well as the venous; and they account at the same time for the very frequent association of *arteritis* with *phlebitis*, particularly in the last stages of febrile and eruptive diseases. These considerations naturally suggest the propriety of having recourse to such measures as may be best suited to individual cases for the prevention of inordinate depression of the energies of life, during the advanced stages of diseases, when we fear the supervention or the existence of *arteritis*; or as may support those energies, whilst we excite the organs whose functions are chiefly to eliminate irritating and hurtful matters from the circulation. By thus opposing too great depression, further deterioration of the blood is more likely to be prevented than by any other indication of cure; whilst the removal of the cause,—the source of irritation of the internal surface of the vessels,—presents a probable chance of the disappearance of its effects. (See *AORTA—Diseases of.*)

ARTHRITIS. See *GOUT.*

ARTS AND EMPLOYMENTS.—CLASSIF.
—**PATHOLOGY.**—*Etiology.*

1. An inquiry into the diseases caused by the prosecution of the various arts of civilised life is of the utmost importance to the scientific professor of medicine in all countries, but particularly in this; for in no other country are the useful arts so extensively prosecuted as in Great Britain. The great importance of the subject has been acknowledged by the success of the able works of RAMAZZINI, MERAT, PATESSIER, and THACKRAH, on the diseases of artisans.

2. As it would be foreign to my plan to take into consideration at this place the diseases occasioned by the numerous arts which furnish employment and subsistence for a very large part of the population of this and many other countries, particularly as these diseases will be considered in their more important relations in other places, and many of them under distinct articles; I will here confine myself to a succinct account of the effects which the prosecution of the various useful arts directly or indirectly produces in the frame; interspersed with a few remarks as to their influence in modifying the characters of various diseases, and as to the means by which their injurious effects may be partially prevented or counteracted.

3. In offering these observations, I will only, in some respects, observe the arrangement adopted by RAMAZZINI, and closely followed by FOURCROY and PATESSIER. This arrangement is founded on the nature of the causes producing the diseases to which artisans are liable. The **FIRST CLASS** of causes consists—1st, *Of confinement, and insufficient ventilation*; 2d, *Of undue exertion*; and, 3d, *Of sedentary habits.* The **SECOND CLASS** comprehends—1st, *Undue exertion of particular parts, and insufficient exercise of other parts*; 2d, *Unnatural or constrained positions in different employments*; and 3d, *Temperature and moisture.* The **THIRD CLASS** embraces those causes which consist of material molecules, and which, coming directly or mediately in contact with the body, in the state either of vapour or of minute disintegration, penetrate the organs, and disorder their functions. These are—1st, *Mineral molecules*; 2d, *Vegetable molecules*; 3d, *Animal molecules*; and, 4th, *Mineral and vegetable molecules acting mechanically.* On the operation and effects of each of these, as being intimately connected with the nature, complexion, and removal of diseases, I proceed to offer a few remarks.

4. **I. CLASS FIRST.**—1st, *The hurtful influence of confinement and of insufficient ventilation* is great in proportion to the youth or early years of those who are thus circumstanced. In the majority of factories, artisans are congregated in great numbers, necessarily confined during the greater part of the day in the same apartment, which, being usually warmed by artificial heat,—by pipes conducting heated air or steam,—have not the air renewed with that rapidity which necessarily obtains in apartments provided with the fire-places in common use. The consequences are, that those confined in them breathe an impurer air than under ordinary circumstances; and experience the debilitating influence occasioned by an atmosphere loaded with an increased quantity of carbonic acid gas and animal effluvia.

5. Persons who have already attained to their full growth, and those particularly who have nearly reached the meridian of life, seldom experience the deleterious effects of confinement under such circumstances, to nearly the same extent as those in early life. When the subject was brought before parliament by Sir ROBERT PEELE, Mr. OWEN, of New Lanark, stated, respecting the children employed in his manufactory, that, although they were extremely well fed, clothed, and lodged, looked fresh, and, to a superficial observer, were healthy in their countenances, yet their limbs were generally deformed, their growth stunted, and they were incapable of making much

progress in the first rudiments of education. This statement, which appears to have been made as a result of large experience, agrees with the observations of other able men. The evidence of Sir ASTLEY COOPER is even still more decided, and is perfectly in accordance with the experience of every competent judge. The result of confinement, this eminent surgeon states, is not only to stunt the growth, but to produce deformity. Every traveller in countries, the population of which consists chiefly of those whose avocations bring them much in the open air, or in agricultural districts, must have remarked not only the much more fully developed frames, and larger lower extremities, of the inhabitants of those parts, but also the more phlogistic or inflammatory characters of their disorders, and their greater vital resistance and powers of restoration when exposed to the causes, or suffering from attacks of disease, than are manifested by the inhabitants of crowded manufacturing towns.

6. Not only is confinement in itself detrimental to the frame, particularly during the epochs of development of the various structures of the body, when air and exercise are nearly as requisite as food to their perfection, but the construction of the apartments, the want of ventilation, the accumulation of animal effluvia, and the moral deprivation consequent upon continued assemblages of persons little under physical and moral control, essentially increase its injurious effects, and co-operate with it in impressing an asthenic character on the frame; in disposing to the formation of tubercles, and to the strumous diathesis; in depressing the vital energies and mental manifestations; and, consequently, in disposing the body the more to the usual exciting causes of disease, and the mind to vicious habits and indulgences.

7. 2d, *Over exertion* is a very frequent cause of disease among many artisans; and, like confinement, it is the more injurious the earlier in life it comes into operation. In the lower animals, particularly in the horse, the consequences of over-exertion are fully manifested. This animal seldom reaches one half of its natural life as employed in this and many other countries. As to the effects of over-exertion on man, much will depend upon his habits and modes of living. When well fed, and of regular habits, its injurious consequences are neither so great, nor so soon appear, as when he is poorly fed or addicted to the use of spirituous liquors.

8. Over-exertion shortens life. 1st, by injuring the continuity, cohesion, or relative situation of various parts; 2d, by inducing that degree of exhaustion which runs on to irremediable or fatal disease; and, 3d, by that gradual and insensible expenditure of vital influence, beyond the power of reinforcing it, whereby the mean duration of human life is shortened. The trades which chiefly illustrate the above positions are coal-heavers, navigators or ballast-dredgers, smiths, miners, &c.

9. It should not be overlooked, that in many trades the artisan is not only subjected to confinement in close and imperfectly ventilated apartments, but is at the same time obliged to over-exert his physical powers. In such cases the ill effects are necessarily greatly augmented; more especially in children or very young persons, who are naturally impatient both of confinement and

over-exertion; and in them particularly are the injurious effects, moral as well as physical, chiefly manifested. Many of those who become the most drunken, immoral, or feloniously depraved, have been initiated in vice from the associations formed in factories.

10. 3d, *Sedentary habits*, are also adverse to health, but only in a negative manner, as respects persons living in well ventilated and wholesome situations. The simple neglect of due exercise, however, is after a time generally productive of disease, owing both to its effects upon the nervous and muscular energies — the manifestation of all our functions being improved by a moderate exertion of them — and to its influence on the secretions and excretions, which require a certain degree of muscular exercise for their promotion. Literary men suffer in a particular manner from want of bodily exercise, chiefly owing to the over-exertion of the mental powers, the bent position of the trunk, and the stagnant air of close apartments. Clerks, and various artisans, suffer also from the same cause, particularly tailors, shoemakers, watchmakers, weavers, jewellers, &c. In some of these, the pressure made upon the lower part of the sternum and stomach proves very injurious.

11. Mr. DOBSON furnishes very instructive information as to the effects of confinement to a particular posture and in a close atmosphere upon tailors. Of 334 men, employed by Stultz & Co., in London, six are above sixty years of age; fourteen about fifty; and the greater number of the remainder about forty. Three of the six above sixty have curvature of the spine. Their most common affections are dyspepsia, diarrhoea, headach, giddiness, and anal fistula, to which latter they are so subject that they have a "fistula club." They attribute their complaints to the bent posture of their bodies for thirteen hours a day, and the heat of the work-shop. Tailors are the most intemperate set of workmen in London. A large proportion of them die annually of phthisis. (ТИАКРАН, &c. p. 17.) The diseases most commonly observed amongst shoemakers are chronic inflammations of the stomach, liver, and bowels, occasioned by the pressure of the last on the lower part of the sternum, where it occasions, in those who are long-lived, a considerable depression.

12. The sitting posture, when long or habitually continued, is very hurtful in persons of sedentary habits. M. PATISSIER remarks, that it causes the lymphatic to predominate over the nervous, sanguiferous, and muscular diathesis. Artisans and others who adopt it early in life, rarely acquire vigorous constitutions, or reach old age, although old age soon overtakes them. Persons with this habit soon become subject to dyspeptic disorders, to affections of the kidneys and urinary organs, to constipation, hæmorrhoids, various cachectic affections, obesity, and, in females, to fluor albus, and difficult or irregular menstruation. When, in addition to a long-continued sitting posture, the trunk is bent, and pressure frequently made over the epigastrium and sternum, as with shoemakers, weavers, attorneys' or bankers' clerks, &c., gastrodynia, nervous palpitations, chronic gastritis, pulmonary consumption, chronic pericarditis, and imperfect digestion, excretion, and assimilation, amounting

even to complete asthenia, are the not infrequent results. The hurtful effects of the sitting posture and bent state of the trunk are much increased by deficiency of food on the one hand, or by too full living on the other; and by habitual excesses of any kind, but particularly in the use of ardent spirits.

13. Literary men who are of sedentary habits are liable both to the disorders which result therefrom and to those which depend upon over-exertion of the mental faculties. Amongst the latter, melancholy, hypochondriasis, cephalalgia, paralysis, apoplexy, palsy, inflammation of the brain or of its membranes, mania, and softening of the brain, hold a prominent place. All these evils are, however, in a great measure prevented by moderate diet and regimen, by avoiding excesses of every description, by regular and moderate exercise in the open air, by early rising, by sufficient but not too much sleep, with attention to the digestive organs, and to the promotion of the abdominal secretions and excretions.

14. II. CLASS SECOND.—1st, *The undue exertion of particular organs, with or without insufficient exercise of other parts*, is often productive of most injurious effects; but much of the evils imputed to this cause by MM. GOSSE, MERAT, and PATISSIER, are either imaginary, or merely matter of occasional coincidence. A. The consequences of undue muscular exertion are chiefly hernia, aneurisms of the large vessels, dilatation of the cavities of the heart, hæmorrhages from the lungs or nose, injuries of the ligaments and intervertebral spaces, sprains and lacerations of muscles; and are chiefly met with among those occupations that are of a laborious kind, as porters, coal-heavers, draymen, &c. Of all these injurious consequences, herniæ are very much the most frequent. Amongst all those persons who bring the back and superior extremities into frequent energetic exercise, it will be observed that the muscles of these parts are not infrequently developed either at the expense of those of the lower extremities, or to a degree far beyond them. This partly arises from the shuffling gait of those persons, and from not throwing the gastrocnemii muscles into action.

15. B. *Over-exertion of the vocal organs* is not infrequently productive of disease. The affections which proceed from this cause are hæmoptysis, laryngeal phthisis, aphonia, œdema of the glottis; functional, and subsequently organic, diseases of the heart and large vessels; nervous and cerebral affections. The persons most liable to be affected by this cause are public singers and orators; but I believe that the ill effects resulting from it, in any of the above states of disease, are not so great nor so frequent as some writers have stated. Much of the mischief imputed to this cause is referrible rather to the enthusiasm of singers and orators, to the passions which are called up during the exercise of their powers, and to the various dissipations and exposures into which their avocations lead them. The occurrence of musico-mania from excessive musical enthusiasm is known to all physicians. It is obvious that the first signs of the accession of the above diseases in the persons of singers and orators, require strict avoidance of the cause.

16. C. *The continued or intense action of light on the eyes, and application of them to small objects*, as amongst workers at iron forges and fur-

naces, engravers, watchmakers, embroiderers, painters, &c., are often followed by injury to, or entire loss of, sight; persons thus employed being liable to amaurosis, cataract, inflammation of the retina, iris, or capsule of the lens, and to shortsightedness, owing to the more convex form the eye acquires from continued compression by the muscles attached to the eye-balls.

17. 2d, *Unnatural or constrained positions* are extremely injurious in the prosecution of any art or employment. Occupations that require long-continued standing have been said to be productive of varices in the lower extremities; but I am not aware that such affections are more common amongst printers, who usually stand at the frames, than in other persons. There is no doubt of undue pressure made upon any particular part of the body in the exercise of any art or trade, or even slight pressure when long continued, being most injurious. This is remarkably the case when the pressure is made upon the abdomen, particularly over the epigastrium, and still more so if it impede the actions of the respiratory muscles. Various occupations, which are injurious from this cause, might be pursued with great assiduity by attending to those circumstances, many of them trivial, which may remove or counteract it. Thus clerks, and others, who are often injured by stooping over a desk, and by pressing the chest against it, as well as by the sitting posture too long continued, would be much benefited by frequently, or even occasionally, standing at a raised desk. Tailors and shoemakers are also very liable to suffer from this cause. The stooping posture is not infrequently productive of cerebral and nervous affections; hence the frequency of them in gardeners. Working in constrained positions shows its effects most decidedly in miners and colliers, who labour chiefly in the sitting or kneeling posture, frequently with the body bent in the greatest degree, in an unnatural atmosphere, often containing hydrogen, or carbureted hydrogen, and carbonic acid gases, and with artificial light. They are, moreover, exposed to changes of air, and occasionally work with their feet in water. They are generally spare men, with slightly curved spine, and bowed legs. When the dirt with which their skin is usually loaded is removed, the complexion seems sallow and unhealthy. Their complaints are asthma, rheumatism, disorders of the head, intolerance of light, &c., evidently resulting from the circumstance just stated connected with their employment, and their exclusion from the beneficial influence of sunshine, light, and air. They are not generally very intemperate, yet they seldom live beyond fifty.

18. 3d, *Temperature and moisture*, and particularly rapid vicissitudes of them, are extremely productive of disease amongst artisans, but chiefly from negligence, and the want of caution in exposures to them. Forgers, glass-blowers, brass and iron founders, bakers, brewers and various other classes of artisans, are liable to be affected by the high temperature in which they work, and by imprudent exposure to cold when perspiring, and often without any additional clothing. The most frequent consequences are checked perspirations, producing catarrhs, rheumatism, bronchitis, asthma, and inflammation of the lungs, or of some one of the abdominal viscera.

19. a. The bad effects of moisture only are pro-

blematical, or at least not very remarkable. It is only from the circumstance of its being either the cause of a greatly depressed temperature, or the very common vehicle in which other agents of disease are dissolved, and thereby diffused in the air, or applied in a more active state to the different organs, particularly the respiratory, that it becomes a very active agent of disease, as is demonstrated by the etiology of the intertropical and malignant diseases. When exposure of the external surface of the body to moisture is injurious, the mischief is caused chiefly by the depressing effects of the low temperature which it occasions. The animal heat is less rapidly carried off by entire submersion in water, than by aspersion merely. In the former case there is no evaporation, in the latter more or less evaporation takes place, and much cold is thereby generated. The histories of shipwrecks abound in proofs of this position. Dr. CURRIE, in his well known work, has adduced a striking example of it. It is owing to the evaporation which takes place from damp or moist clothes, and the consequent rapid reduction of their temperature, that disease is occasioned by them.

20. Artisans who, from the laborious nature of their occupations, perspire copiously, and thereby render their clothes damp, seldom suffer from this cause while they continue their labours; but when they relax, or desist altogether, their wearing the moistened clothes, particularly in a state of exhaustion, is frequently productive of disease. Inattention to, or inability of, changing damp or wet clothes, are the most common causes of the disorders met with in milkmen, gardeners, fishermen, washerwomen, fullers, water carriers, and persons whose occupations are chiefly out of doors. In marshy or unhealthy localities, the effects of this cause are greatly increased. The steepers and cleaners of hemp and flax are extremely liable to intermittents, owing to the conjunction of vegetable effluvia with moisture. Even persons constantly employed in crowded factories, where the stagnant air becomes loaded with the foul vapours exhaled from the lungs of a number of persons, may have their clothes so saturated with moisture as thereby to occasion the usual consequences of cold, when exposed to a drier or opener air. It should be kept in recollection, that cold, when it continues to act for any time upon the frame, is sedative—it depresses the vital influence; and, when acting partially, or directed to parts of the body only, that it is one of the most productive causes of altered energy and sensibility of the nervous system of such part, of irregular distributions of vital influence and of the blood, and consequently fruitful of inflammations, and of morbid discharges and actions.

21. *b.* The prevention of diseases resulting from the description of causes adduced under this head is important. Wearing flannel next the skin is amongst the most efficacious. For those who are exposed to moisture from out-of-door vocations, the use of external garments of dressed skins, or of tanned leather, or of oil-skin, during the time of exposure, is extremely serviceable, and is generally adopted by the fishermen of northern countries.

22. III. CLASS THIRD.—1st, The mineral molecules, which, either in the form of vapour or of minute disintegration, come in contact directly or

mediately with various parts of the body, are extremely frequent causes of disease in artisans; and some of the maladies they produce are possessed of specific characters.

23. *A.* Mercury is one of the most common causes of the diseases of artificers, particularly workmen in quicksilver mines, glass-platers, gilders of buttons, toys, &c. Dr. GOSSE has remarked the greatly increased sensibility of those persons to cold, even to the slightest diminution of temperature, evidently owing to depression of the vital energy and organic actions, and consequently of the process of animal calorification. Persons long or habitually exposed to fumes of quicksilver are generally affected with ulcerations of the mouth and fauces; painful or rheumatic affections of the periosteum, joints, limbs, and ligaments, particularly after exposure to cold; eruptions on the surface of the body, and all the affections to which the term pseudo-syphilis has been applied; as well as many of those which are usually denominated cachectic. The effects are altogether the same, although slower in their accession and progress, as those which result from a too long continued, but not violent mercurial course.

24. *a.* Amongst the most important of the affections produced by the fumes or oxides of mercury in artisans is the *mercurial palsy*, the *tremblement mercuriel* of the French pathologists. It is almost, but certainly not altogether, peculiar to these persons. Its approach is generally gradual, but occasionally sudden; it usually commences with slight convulsive snatches, followed by agitations and tremors of the affected muscles, particularly those of the arms, which it first attacks, occurring as it commonly does amongst the workers in mercury. If the person continues his employment, the affection extends to the lower extremities and whole body. He becomes incapable of muscular exertion, and even of the avocations requiring the least precision of muscular action. Restlessness, falling out of the teeth, constipation or disorder of the bowels, a dry and brownish state of the skin, slight atonic convulsions, cephalalgia, delirium, great depression of the nervous powers, and of the general health, take place, in which state the patient may continue to live for many years. (MERAT and COLSON.) Although it is chiefly long-continued exposures to mercurial preparations which produce this affection, a single exposure to the fumes, even for a few hours, when they float in the air, may occasion it; the effects being both rapid and violent when their vapours are inhaled with the atmosphere, and act upon the extensive surface of the bronchial tubes and air-cells.

25. *b.* The habits of the workmen exposed to the fumes or oxides of mercury, render the treatment of this affection extremely difficult, owing chiefly to the circumstance of their frequent recourse to spirituous liquors, for the temporary advantage they afford, and to their deferring having recourse to medical aid until the disease becomes confirmed. In recent cases, leaving off the trade that occasioned it will alone produce a cure. In long-continued or confirmed cases, benefit is obtained with much more difficulty; and, when procured, the disorder is extremely apt to return after the slightest exposure to mercurial fumes. DE HAEN prescribed electricity in the cases which

occurred to him. LETTSON recommended sulphur; and I believe that its good effects are very considerable. In a case which lately came before me, of violent cephalalgia, with muscular tremors, &c., after a severe mercurial course, large doses of sulphur merely, given every night in treacle, produced a cure in a few days. Mr. PEARSON chiefly relied upon exposure to a dry and open air. SEMENTINI states, that he obtained uniform advantage from the internal use of the nitrate of silver, beginning with an eighth of a grain, and gradually increasing the dose to three grains in the day. I have lately employed the *tincture of iodine* in two cases of this affection with success; and in one instance I prescribed *strychnine*, but lost sight of the patient before its effects were apparent. Mr. EARLE (*Lond. Med. Gaz.* vol. xi. p. 31.) gave five grains of the extract of conium, three times a day, with benefit.

26. c. It is obvious that it is of importance to be in the possession of plans to prevent the injurious effects of mercury on those employed in the arts in which it is used. These are sufficiently simple, and consist chiefly of common attention to cleanliness, and avoiding the fumes of the mineral during the various parts of the processes of gilding. Workmen should avoid touching the amalgams that are used with the naked hand; and ought to make frequent ablutions, particularly before taking a meal. During the process of volatilising the mercury by heat, the utmost caution should be exercised in performing the operation with a stove in which the current of air is very brisk, so that the fumes may be carried fully up the flue. In most of the manufactories in this country, the stoves are now sufficiently well constructed for this purpose, the carelessness of the artisan being the chief cause of danger from his occupation. M. JUSTIEU states, that the free workmen in the large quicksilver mines at Almaden, who took care to change their whole dress, and attended to cleanliness, were but little affected by their occupation; but that the slaves, who could not afford a change of raiment, and took their meals in the mines generally without ablutions, were subject to swellings of the parotids, aphthous sore throat, salivation, eruptions, and tremors. (*Mém de l'Acad. des Sciences*, 1719, p. 474.)

27. B. Lead. — a. Injurious effects from lead, in the various states in which it is used, are very frequent and often fatal. Its oxides may be carried off in a state of vapour, dissolved in volatile substances, as by turpentine in painting, and thus be inhaled into the lungs, and act most injuriously on the frame. It may also pass into the alimentary canal in various ways, or it may be absorbed from the skin, particularly of the hands, where it will both act locally, and be carried into the system, and produce its effects as when introduced by the two former channels. These effects are chiefly lead colic and paralysis. The workmen employed in lead mines, those who are engaged in procuring it from its ores, who cast it or manufacture its various preparations, and who use them in the different arts, as plumbers, glaziers, painters in oils or water-colours, colour-grinders, type-founders, printers, are the most liable to be affected by lead; but all classes, under certain circumstances, may also experience injurious effects from it. The deleterious nature of this mineral is cer-

tainly very great; but the fatal results are surely not one in three annually, as stated by Sir JOHN SINCLAIR.

28. b. M. MERAT has furnished some very interesting information respecting the frequency of *colica pictorum* in the various classes of artisans who came in contact with any of the different preparations of lead. It is derived from the list, kept at the hospital La Charité, in Paris, in the years 1776 and 1811. The total number in both years were 279. Of these 241 were artisans, whose trades exposed them to the poison of lead, viz. 148 painters, 28 plumbers, 16 potters, 15 porcelain makers, 12 lapidaries, 9 colour-grinders, 3 glass-blowers, 2 glaziers, 2 toy-men, 2 shoemakers, 1 printer, 1 lead miner, 1 shot manufacturer. Of the remainder, 17 belonged to trades exposed to copper. Of the 279 cases, 24 were under twenty years of age, these being chiefly painter boys, not above fifteen; 113 were between nineteen and thirty; 66 between twenty-nine and forty; 38 between thirty-nine and fifty; 28 between forty-nine and sixty; and 10 older than sixty. Among the 279 cases, 15 died, or 5.4 per cent. (See the article COLIC, FROM LEAD.)

29. c. The measures of prevention from the action of the preparations of lead differ in no respect from those which have been stated in relation to mercury (§ 26.). They chiefly consist of strict attention to personal cleanliness. The instructions given by M. MERAT are very complete, but are too particular to be followed by workmen. He recommends that the working clothes should be made of strong compact linen, be changed and washed once or twice a week, and be worn as little as possible out of the workshop; a light impervious cap ought always to be worn on the head. The artisan should never take his meals in the workshop, or without strict ablu-tion of the hands, mouth, and face; and he ought to breakfast before leaving his home.

30. Derangements of the digestive organs ought to be watched with care. If colicky symptoms occur, he should leave off work, and take an aperient. He ought always to guard against constipation. The diet of those exposed to be affected by the preparations of lead is of consequence. It should be light and digestible; and poor acid drinks ought to be avoided, particularly cider, as themselves often containing lead. Various articles of diet have been recommended as calculated to impede the hurtful action of lead on the frame. HOFFMANN mentions brandy — a somewhat dangerous recommendation. Fat food has been accounted preservative. De HAEN states, that the workers in a lead mine in Styria were much affected by a colic and palsy, but, by being told by a quack doctor to eat a good deal of fat, particularly at breakfast, they were exempt from these diseases for three years (*Rat. Med.* p. i. ch. ix.). Similar facts respecting the good effects of fat meat, as a preventative of the effects of lead, are recorded by Sir GEORGE BAKER (*Trans. of Lond. Coll. of Phys.* vol. ii. p. 457.) and Mr. WILSON (*Edin. Phys. and Lit. Essays*, I, p. 521.) Those who work at furnaces in which lead is smelted, fused, or oxidised, should be protected by a strong draught through them. Mr. BRAID, of the extensive mines at Leadhills, informed Professor CHRISTISON (see his most valuable work on *Poisons*, &c. p. 506.), that wherever

furnaces of such a construction have been built, the colic has disappeared.

31. *C. Copper*, although extensively used in the arts, is seldom productive of much disease. *PATISSIER* states, that the workmen in copper become prematurely old, having a meagre and sickly appearance. This is, however, as much owing to their confinement in ill-ventilated places, and in temperance, as to the metal. *MÉRAT* has adduced evidence of their being frequently subject to *colica pictorum*. They are likewise liable to diseases of the respiratory organs,—particularly those engaged in filing the metal; but this is entirely owing to the mechanical irritation occasioned by the finer particles when inhaled into the lungs. Asthma is frequent amongst brass-founders, owing probably to this cause, and partly to the vaporisation of a portion of the zinc with which copper is amalgamated.

32. *D. Zinc, arsenic, and antimony* are seldom productive of hurtful effects amongst artisans; owing probably to the first being chiefly employed in the metallic state, in which it has no effect, although it is deleterious when oxidised; and to the circumstance of arsenic and antimony being generally used in small quantities.

33. *E. The acrid vapours*, which proceed from the *mineral acids*, often produce violent effects when respired; chiefly asphyxia, and severe inflammation of the air-passages; but they are easily guarded against, and chiefly by operating in nearly open places. Persons who prepare articles for gilding, by cleaning them in aquafortis, are equally liable to respire the vapours of these acids, but may avoid them with even a moderate share of caution. The inflammations of the respiratory organs occasioned by them, differ merely in respect of their intensity, from the same diseases proceeding in an acute form from other causes. Chlorine gas, when respired in considerable quantity, produces inflammation of the air passages. The chief effects of habitual exposure to it are acidities and other complaints of the stomach. The trades in which workmen are exposed to chlorine do not seem to be unwholesome. Corpulent men are soon reduced by it to their natural size. During the epidemic fever that raged all over Ireland from 1816 to 1819, the people at the chemical manufactory at Belfast were entirely exempt from it.

34. 2d, *Molecules of animal matter in a state of decay* are frequently productive of disease, both in persons whose avocations expose them frequently to this cause, and in those who approach it only incidentally. Nightmen are chiefly exposed to this source of disease, particularly in Paris. The gases evolved when emptying the *fosses d'aisances* of that capital are frequently productive of serious and even fatal consequences. The exact nature of these varies with the vapours evolved. Ammoniacal vapours usually occasion what the French term *la mitte*: sulphuretted hydrogen, hydro-sulphuretted ammoniacal gases, and azote, produce *le plomb*.

35. *A. The symptoms of la mitte* are smarting of the eyes, with the sensation of sharp or pungent odour and uncomfortable feeling about the nose. To these succeed pain, extending to the forehead, and discharge from the eyes, occasionally with blindness enduring for two or three days. These effects, if not very intense, generally pass off by

shading the eyes, and exposure to the open air; if they are more severe, the application of cold epithems to the eyes, and protecting them from the light, are usually efficacious.

36. *B. Le plomb* is of two kinds; 1st, that occasioned by azote, and which is simply *ASPHYXY* (which see) from the privation of respirable air, attended with coma or stupor; 2d, that caused by sulphuretted hydrogen and hydro-sulphuretted ammoniacal gases, which is the most dangerous and common, and is generally attended with convulsions. (See *POISONS*.) The former is commonly prevented by a free circulation of air; the latter is avoided by employing the chlorurets of lime or of soda, a solution of which is poured in the privies, and reservoirs or drains, shortly before they are emptied. (See *Treatment of ASPHYXY* and of *POISONING by deleterious Gases*.)

37. *C. The animal effluvia* proceeding from slaughter-houses, dissecting-rooms, chandlery or adipocire manufactories, and other places where animal substances are manufactured or employed in the arts, are seldom so concentrated as to be productive of disease; but there can be no rational doubt of their unwholesome influence when concentrated, or accumulated in a stagnant atmosphere. The liability of butchers and cooks to be corpulent has been absurdly enough ascribed by some superficial writers to the absorption of nutritive particles from the air, without attending to the fact of a much larger quantity of animal food being taken by them than by any other class of persons.

38. *DR. WITHERING* had noticed (Letter to *DR. BEDDOES*, 1793) the comparative exemption of butchers and catgut makers from phthisis. *M. PATISSIER* has made the same remark; and *DR. BEDDOES* has added to these employments soap-boilers, and the fishermen and fish-wives in the vicinity of Edinburgh. Glue and size boilers are exposed to putrid and ammoniacal exhalations from the decomposition of animal refuse. But these workmen are generally fresh-looking and robust. A similar observation is applicable to *bucketram manufacturers*. *Tanners* are subject to animal vapours; but so combined with the odours of lime and tan as entirely to counteract any injurious effect which the former might produce. They are much exposed to wet and cold; yet they are generally healthy, robust, and tolerably exempt from pectoral diseases, particularly consumption. *MR. THACKRAH* states, that he has carefully inquired at several tan-yards, and could not hear of a single example of this disease.

39. 3d, *Vegetable molecules*.—Corn-millers suffer remarkably from breathing an air loaded with the particles of flour. They are chiefly affected by indigestion, asthma, and morning coughs with expectoration, terminating either in consumption or in asthma; and are generally pale, sickly, and short-lived. This is the case only with those who work in the mills. Those amongst them who labour in the open air with the carts are not thus affected; but, as other persons raising heavy weights, are subject to herniæ. *Maltsters* are liable to the same diseases, arising from the same agents, and from the heated and sulphureous air of the kilns. *Bakers* are exposed to similar causes, but to a much less extent, and suffer accordingly—chiefly from cough, asthma, affections of the stomach, rheumatism, and a peculiar chronic

eruption on the skin. *Snuff-makers* are exposed to the dust of the tobacco; but they are not so much affected by it as may be expected. They chiefly complain of disorders of the head, stomach, and air-tubes: of the former, from the narcotic effect of this vegetable; and of the last from its irritation. The narcotic odour to which *tobacco manufacturers* are liable is not productive of any very appreciable mischief, owing to their having become insensible to its influence.

40. 4th, I shall here briefly notice those trades, the workmen in which experience the very injurious effects of inhaling an atmosphere in which various *vegetable, animal, or mineral molecules are floating*, — causes which, although very dissimilar in themselves, generally act in nearly a similar manner — namely, by irritating the bronchial surface, and superinducing various modifications of disease, according to peculiarities of constitution, temperament, and habits of life. — *a.* The artisans who suffer the most from these causes are dry-grinders and needle-pointers; edge-tool, gun-barrel, and other grinders; flax-dressers, and pearl and horn button makers; iron, brass, and other metal filers; stone-cutters, miners, and quarriers, particularly in sandstone; wool-carders and feather-dressers, sawyers, turners, weavers, and starch-makers. All these suffer more or less, generally in the order here followed (needle-pointers and dry-grinders the most, and starch-makers the least), from chronic bronchitis, in one or other of its modifications; in some, from the spasm of the bronchi thereby occasioned, with the symptoms of asthma predominating; in others, with those of chronic inflammation extending to the lungs; in a few, with pulmonary emphysema; and in many, with tubercular and cretaceous formations. The most inflammatory effects seem to result from needle-pointing, dry-grinding, and stone-cutting; whilst the more asthmatic affections proceed from the horn and pearl button manufacturing. These workmen seldom live above forty years, and the greater number not beyond thirty or thirty-five. They often experience but little inconvenience till some time before the fatal disease takes place; but they are as often affected in early life, particularly pearl and horn button makers, the disease subsequently assuming an asthmatic character.

41. *b.* Various means have been invented in order to prevent the molecules or dust arising in these trades from accumulating and being inhaled into the lungs of the workmen; but nearly every measure hitherto advised has been neglected by them. Amongst other contrivances, the muzzle of damp crape recommended by Dr. JONESTONE, the sponge by Dr. GOSSE, and M. D'ARCEL'S "fourneau d'appel," which is, however, not known in this country, may be named. The best means yet devised seems to be that invented by Mr. ABRAHAM'S of Sheffield, in which magnetic attraction is employed to arrest the floating metallic particles. This, as well as the use of the "damp bag" suspended over the stone, in grinding and pearl button turning, are most useful inventions. In mining, quarrying, or cutting stones, dry grinding, &c., much good would probably result from having moistened or wet woollen curtains suspended over the heads of the workmen, and in such a way as to be agitated through the air of the place. The simpler the means, and the less

trouble required in their use, the more likely are they to be adopted.

42. *c.* In respect of the treatment of the pulmonary diseases which result from these causes, very little difference from that employed under ordinary circumstances is required. The frequent use of emetics is adopted by the workmen themselves; and there can be no doubt of their utility in the most of the diseases of the air passages. The other means of cure are fully noticed in their respective places.

CLASSIF. — 2. Class, Nervous diseases; 1. Order, Comatose Affections (Cullen) 4. Class, Diseases of the Nervous Function; 4. Order, Affecting the Sensorial Powers (Good). I. CLASS, III. ORDER (Author, see Preface).

1. DEFIN. *Suspended animation proceeding from a primary arrest of the respiratory actions, the other functions being thereby abolished.*

2. ASPHYXY, according to its etymology, should be defined the cessation of the action of the heart. In this case it would be synonymous with certain forms of syncope, from which, however, it most essentially differs. Yet even in syncope the most complete, the action of the heart never altogether ceases; it is only unusually weakened, and previously to respiration being affected. Attention to the phenomena to which the term asphyxia has been so long applied, will inform us that the actions of respiration are primarily arrested; that the functions of circulation are subsequently abolished; and that death is the result of this succession of events. It may, however, be stated, in justification of the change of signification which this term has undergone, that there is no state of the system from which recovery is possible, that is characterised by a more complete abolition of the action of the heart than this, although it takes place secondarily only, from the arrest of the respiratory functions.

3. Asphyxy has been very generally viewed as proceeding from causes which act in various ways; and the opinions respecting their nature and mode of operation have been extremely deficient in precision and accuracy. According to the meaning which I have attached to the term, as stated above, asphyxy can only occur in a direct or primary form, from causes which either exclude

the air from the lungs, prevent its renewal, or abstract that constituent of it which is requisite to the respiratory functions. Authors have, however, included, under the head of asphyxies, those states of suspended animation which proceed from the respiration of deleterious gases; and Dr. Good has comprised under it death or suspended animation from lightning and from intense cold. In every case of the action of deleterious gases, of lightning, and of intense cold upon the system, the respiratory organs, although one of the channels for the action of the latter, are not the first to have their functions arrested. The action of all these agents is primarily exerted upon the ganglial and nervous systems; and, owing to their effects upon these systems, the function of the brain, of respiration, circulation, &c. are subsequently abolished. As the action of the greater number of deleterious gases, when respired, is similar to that of other irritating and narcotic poisons, I shall consider them under the head of *gaseous poisons* (see *POISONS*). When, however, they are of such a kind, or are present to such an extent, as to irritate violently the larynx, and, by exciting spasm of it, to exclude the air, or so as to displace, and to occupy the room of, the respirable atmosphere, their action is similar to other agents primarily occasioning simple asphyxy; and they therefore require no further notice than by adducing them as causes of this state. In respect of the influence of cold and lightning upon the frame, it may be observed that, although exciting and concurrent causes of asphyxy, and producing this, with other changes, in the vital functions, but in very different ways, they act directly upon the nervous system, and give rise to asphyxy only secondarily; and, like the more poisonous gases, chiefly through the medium of this system, particularly that part of it which presides over the functions of the brain and heart. Their action will therefore fall under different heads.

4. I. CAUSES.—Asphyxy takes place in a primary and simple form, from whatever excludes, or prevents the renewal of, air in the lungs of a healthy person, or consecutively upon other affections or diseases, especially those affecting the nervous system, and particularly the respiratory class of nerves. In the former state of the frame it is an *idiopathic* or *essential* affection; in which light it will be chiefly viewed in this place: in the latter it is *symptomatic*, or rather one of the modes in which disease terminates life. Those states of asphyxy may proceed, *first*, from a primary cessation of the mechanical phenomena of respiration, and, *secondly*, from a primary default of the chemical changes which take place during the respiratory actions.

5. To the first of these is to be referred the asphyxy which depends upon inaction of the respiratory muscles (*A.*); and (*B.*) upon deficient expansion of the lungs, the inspiratory muscles performing their functions. *A.* Deficient or impossible action of the inspiratory muscles proceeds, 1st, from mechanical obstacles applied to them, as in the instances of death occasioned by earth falling upon the trunk of the body, and pressing it so strongly as to prevent them from expanding the thorax: 2d, from deficient or interrupted influence of the nerves supplying these muscles, as from injuries or division of the pneu-

mogastric nerve; injury or pressure upon the medulla oblongata or spinal chord, either from fracture or dislocation of the spine, particularly of its cervical portion; and from the paralysis of the nervous system occasioned by a stroke of lightning, or any other cause abolishing its energy: and, 3d, from want of activity, or deficient irritability of the inspiratory muscles themselves, as from the benumbing influence of cold, and the suspended animation of new-born infants.

6. *B.* The asphyxy which proceeds from a deficient expansion of the lungs, is generally owing, 1st, to mechanical impediments, as the passage of some of the abdominal viscera through the diaphragm, the accumulation of fluids in the pleura, or similar causes: and, 2d, to paralysis of the nervous energy of the lungs, as in cases of death from cold, from lightning, from various poisonous gases, &c.; whereby the vital expansibility of the organ is abolished, along with the other respiratory actions.

7. The second class of causes, or those which act by impeding or abolishing the chemical changes effected by respiration, may be referred to two heads:—1st, Those which present a mechanical obstacle to the entrance of air into the lungs, as strangulation; submersion; the introduction of foreign bodies into the larynx, trachea, or even the large bronchi: and, 2d, Those which consist of a deficiency of respirable air, as a too rarified atmosphere, or the presence of azote, hydrogen, carburetted hydrogen, sulphuretted hydrogen, or indeed of any of the deleterious gases. It is evident, however, that asphyxy is often occasioned by the combined operation of more than one of its proximate causes. Thus it may proceed from paralysis of the respiratory muscles, and of the nervous energy of the lungs themselves; and hence be characterised by abolition of the respiratory efforts, by deficiency of the expansive power of the organ, and by arrest of the chemical changes which take place during respiration: and, on the other hand, several of the remote causes act by individually producing more than one of the pathological conditions now specified.

8. II. CHARACTERISTIC PHENOMENA OF ASPHYXY.

—i. When asphyxy takes place slowly, especially from causes which interrupt the nervous influence actuating the respiratory muscles, it commences with greater or less difficulty of elevating the thorax; anxiety, with urgent desire to inspire, and constant attempts to fill the lungs, giving rise to continued gaspings, or quick, short, and imperfect respiratory efforts; pandiculation; vertigo; failing of consciousness and sensation; sometimes to convulsive movements both of the limbs and trunk, followed by immobility of the parietes of the thorax and abdominal muscles, weak and languid pulsation of the heart, and absence of pulse at the wrist; the face is coloured, livid, tumid, injected, and its veins distended; the hands and feet, as well as the face, present a reddish violet hue; and the cutaneous surface patches of a similar tint. At last the circulation is entirely arrested, and asphyxy is complete. The animal temperature, however, and the absence of rigidity of the muscles, continue for a long time afterwards,—almost always for a much longer period than from death under other circumstances, and from other proximate causes.

9. These phenomena vary, particularly as respects the rapidity of their progress, according to the causes whence they proceed, and to the extent to which air is excluded from the lungs. Where no obstacle to the action of the inspiratory muscles is present,—the obstruction to respiration existing in the air passages,—the efforts to renew the air in the lungs are much more convulsive and laborious. The anxiety is extreme, but of short duration, and rapidly followed by abolition of consciousness, voluntary motion, and of the functions of circulation. In this case the description of SHAKESPEARE is physiologically accurate:—
 “But see! his face is black and full of blood;
 His eyeballs further out than when he lived,
 Staring full chastly, like a strangled man;
 His hair upreared; his nostrils stretch'd with struggling;
 His hands abroad display'd, as one that grasp'd
 And tugg'd for life, and was by strength subdued.”

10. In cases where asphyxy arises from a sudden abolition of the nervous influence of the respiratory muscles, as from injuries inflicted on the medulla oblongata, &c., or when the trunk of the body is so compressed as to prevent all action of these muscles, but particularly when it proceeds from the former cause, the phenomena supervene and succeed each other with great rapidity; but generally in the order in which I have enumerated them, excepting that all respiratory efforts are instantly suppressed. In drowning, however, the progress of the symptoms are less rapid and somewhat different, as will be shown in the sequel.

11. ii. The duration of life in cases of asphyxy is very different, according as the causes which occasion it act with greater or less promptness, or more or less perfectly, in preventing the renewal of air in the lungs. In general, the more slowly that abolition of the respiratory function takes place, as in cases of drowning, the longer does the action of the heart continue, although feebly and slowly, even after respiration has ceased; and to this circumstance, as well as to the fluidity of the blood, which is long preserved, is owing the power we possess of recalling the asphyxied to life; the more slowly the state of asphyxy supervenes, the longer the person retains the ability of being reanimated, and *vice versa*.

12. The length of time, however, after which resuscitation cannot be accomplished, is necessarily varied by different circumstances; and not only by the causes of asphyxy, and their modes of operation, but also the strength of constitution, age, and previous health of the person, and the manner in which abstraction of air has taken place. Much will also depend upon the changes which the asphyxy has produced in the brain,—the degree of congestion, or the occurrence of extravasation there,—circumstances which, when present to any very considerable extent, more particularly the latter, will generally preclude the possibility of reanimation.

13. iii. *Appearances observed on dissection of asphyxied persons.*—A reddish or violet red hue of the countenance and various parts of the surface of the body, which continues to retain its warmth an unusual length of time after death: this tint does not arise from the position of the body after death; and is chiefly seated in the mucous or vascular tissue of the skin, which, upon incision, allows the blood to escape in a state of fluidity. The eyes are bright and pro-

minent; the mouth sometimes natural, at other times expressive of suffering; the limbs are rigid, and continue in this state unusually long, after having been late in assuming it. The veins and sinuses of the brain generally are filled with a dark fluid or semi-fluid blood; the substance and cavities of the brain are not otherwise materially altered. The base of the tongue is generally full or injected, and even tumefied, and its papillae developed; the mucous membrane of the larynx, trachea, and bronchi, is injected and red—the colour becoming darker as we descend from the larynx to the bronchial ramifications, where it assumes a violet or reddish brown tint. Their smaller branches often contain a little sanguineous frothy mucus. The lungs are distended, rise around the pericardium, and present a brown or blackish brown hue; their parenchyma, when divided, are of a redder tint, but give out, upon pressure, large drops of a thick, fluid, and very black blood. The liver, spleen, and kidneys are gorged with blood, presenting a similar appearance. The veins of the heart are congested; and its right cavities, the vena cava, and other large veins, are engorged with black and semi-coagulated or fluid blood.

14. III. THEORY OF ASPHYXY.—It is chiefly to GOODWIN and BICHAT that we are indebted for the near approaches which have recently been made to a satisfactory and consistent theory of asphyxy, upon which a rational mode of treatment may be based. The venous blood sent by the right ventricle to the lungs, which contain a diminished quantity of air calculated to convert it into arterial blood, is returned to the left side of the heart, but slightly changed from its venous state, from whence it is propelled through the arteries to the different organs. The consequence of the imperfect changes effected in the blood, owing to the interruption or cessation of the respiratory actions, is imperfect excitation of the most important organs of the body; and in proportion as the blood sent from the left side of the heart is possessed of more of the venous characters, the absence of excitation is more manifest, until, as respects the brain, and lungs particularly, which are the first of all the organs to experience the effects resulting from the circulation of venous blood, a sedative or stupifying effect, but negative in respect of its nature, is produced upon them; as is frequently evinced on the brain in cases where asphyxy takes place slowly, and when the blood sent from the left side of the heart is completely venous in its characters.

15. In tracing the phenomena it will be observed, that the capillary system of the lungs is the first to experience a loss of their vital tone and undergo congestion. This arises from the following causes:—1st, The absence of the usual stimulus of pure air in the air-cells: 2d, The circumstance of their being the first to receive the blood after being returned from other parts of the body fully charged with venous properties: 3d, The cessation of the mechanical actions of respiration; and, with them, of the expansive motions of the lungs themselves: 4th, The arrest of those changes which the blood undergoes from oxygenated air, and the influence of a darker blood than usual upon the pulmonary vessels: 5th, The loss of nervous influence, arising from the sedative effect of venous blood upon the

nervous centres, when circulating in arterial vessels: and, 6th, The circumstance of the systemic capillary vessels retaining their tonicity and power of reacting, for a longer time, upon their contents, when circulating venous blood, than the pulmonary capillaries; consequently the blood is returned by them into the veins, and thence to the right side of the heart to be sent to the lungs, which are the first, from this and the foregoing causes, to experience congestion, and to lose the power of restoring it to the left auricle. Thus it will be seen, that the interruption to the circulation commences in the capillary system of the lungs, in consequence of the stop put to the mechanical and vital actions of this organ; and that the heart, which does not cease to contract until the functions of the lungs and brain have been abolished, no longer is supplied with blood from the lungs; the left side of the heart being thus the *ultimum moriens*.

16. The early and manifest effects of asphyxy on the brain have been fully proved by the experiments of BICHAT. This organ is deprived of its functions, and the comatose state is rapidly and profoundly expressed; the venous blood conveyed to it, chiefly from its negative effects, giving rise to all the phenomena usually occasioned by a narcotic poison. Even the heart itself, although the last of the three organs to experience the effect produced by the circulation of venous blood, is soon enfeebled in its action. This evidently arises partly from the abolition of the functions of the brain, and partly, or even in a greater degree, from the circulation of dark blood to the ganglia and nerves, whence the heart derives its action, and to its proper structure. But the experiments of Dr. EDWARDS, Dr. WILLIAMS, and Dr. KAY show that the circulation of dark blood does not destroy the irritability of muscles, but that it is a less powerful supporter of this property; and consequently that the irritability of the heart is not abolished, as BICHAT supposed, but only insufficiently excited. Indeed, if this property were destroyed, resuscitation would be impossible.

17. The long continuance of the animal heat after the total cessation of the heart's action can only be explained by the integrity of the vital energies of the frame at the time of the event, by the continued fluidity of the blood, and the circulatory or oscillatory motion of this fluid in the systemic capillary system for a considerable time after the heart has ceased to contract,—phenomena, which have been satisfactorily observed in cases of asphyxy. The patches of lividity, and the dark colour of the surface, depend upon the injection of the capillaries of the surface with dark blood, and the engorgement of the veins. The slow accession of rigidity of the limbs after death is referrible to the longer duration of the animal temperature, and the fluidity of the blood than in other cases; and to these causes also are to be imputed the possibility of resuscitation after a longer period from the cessation of respiration than in any other morbid condition of the frame. The marked rigidity of the limbs, after the body is quite cold, must be chiefly imputed to the perfect state of the vital energies when asphyxia took place.

18. It has long been observed that the body of an asphyxied person appears to contain much more blood than that of an individual who has

died in a different way. BICHAT explains this by supposing that the organs receiving venous blood, which is devoid of the materials necessary to nutrition, yield all the fluids which they usually furnish without appropriating those which they usually do under other circumstances; so that the quantity of blood is actually increased, particularly in cases where the asphyxy takes place slowly. In proof of the accuracy of this view, it has been stated that, when asphyxy occurs suddenly, and the functions cease rapidly, less engorgement of the venous system and of the lungs is observed, than when death is caused more slowly, as in the case of asphyxy from burning charcoal. Perhaps the quantity of blood in the system seems greater from the circumstance of its fluidity, or rather the absence of coagulation; for when this takes place, the serum of the blood partly escapes into the shut cavities after death, and exudes through the vessels and tissues.

19. From the foregoing, therefore, it may be concluded that the cessation of the actions of respiration,—first the mechanical or muscular actions, next the vital or expansive motions of the lungs,—is soon followed by an arrest of the pulmonary circulation, afterwards by abolition of the nervous functions and influence, and lastly by cessation of the heart's action, in consequence of the blood not being restored to the left auricle and ventricle; the latter of which, however, continues to contract as long as blood is sent to it. Hence, as respects the circulation, first, stagnation of the blood in the pulmonary capillaries upon the cessation of respiration takes place; next, a deficient supply of blood to the left side of the heart; and, lastly, an accumulation of it in the pulmonary arteries, and right auricle and ventricle, which are no longer able to overcome the resistance opposed to its passage in the congested pulmonary vessels. Thus it will be seen that the left ventricle is actually the *ultimum moriens*, and not the right, as supposed by many. Upon this view of the procession of phenomena in death from asphyxia, our endeavours to restore animation are founded.

20. IV. THE VARIETIES OF ASPHYXIA, in a practical as well as physiological point of view, deserve particular notice. The respiration of several gases is often followed by fatal consequences; but as asphyxy is only one of the deleterious effects they occasion, I have considered them in another place (see Poisons—Gaseous). Of all gaseous bodies from which asphyxy may arise, azote and hydrogen alone act simply by producing asphyxy; and they have this effect only when they are present in considerable quantity in the air, or when they are respired for some time. The effects which they produce differ in no respect, in the present state of our knowledge, from those described above.

21. A. *Asphyxy from submersion*.—a. There are various circumstances, both proper to the individual, and connected with the submersion, which will modify the resulting asphyxy, and should be taken into account in our endeavours to restore animation. When a person is immersed in water, he is seized with an urgent feeling of anxiety at his breast; his pulse becomes weak and frequent. He struggles to relieve his distress, and thereby rises to the surface of the water, and throws out some air from his lungs. His anxiety continues

to increase, and his pulse becomes weaker; his struggles are renewed with more violence; he rises to the surface again, throws out more air from the lungs, and makes hurried attempts to inspire, and in some of these attempts a quantity of water goes down the throat with the air, and excites cough and spasm of the glottis. These efforts tend to determine blood to the head, which, owing to the impeded state of respiration, partakes of the venous properties; and rapidly induces, from this circumstance as well as from the pressure it occasions, insensibility, loss of voluntary motion, slight lividity of the surface of the body, particularly of the face, loss of pulse, relaxation of the sphincters, and as the body sinks to the bottom, the expulsion of a portion of the air contained in the chest.

22. *b.* On dissection, nearly the same appearances as those already described are found. In addition to these, a frothy fluid is met with in the trachea, and ramifications of the bronchi, with some water, the quantity of which varies in different cases. From Dr. GOODWIN'S very satisfactory experiments, confirmed by Mr. COLEMAN and Professor MEYER, it appears that this small quantity of water enters during the struggles to inspire, and, mixing with the mucus of the bronchi, forms a frothy fluid, insufficient, however, to occasion the fatal changes in drowning. A considerable quantity of fluid is found in the stomach. According to Dr. CURRY, the vessels of the brain are not particularly distended; but there are exceptions to this. Dr. BENGER, of Geneva, found that the air remaining in the lungs had lost nearly all its oxygen. Mr. COLEMAN states that the left ventricle of the heart is never entirely empty, it generally containing about half the quantity of that found in the right ventricle; and that a little blood is also found in the aorta.

23. *c.* In cases where a person, in falling into the water, has been struck on the head and stunned, or is intoxicated, or benumbed with the cold and fright, the efforts at preservation will scarcely be made, and the case will be more completely that of simple asphyxia. In cases of this description the countenance is generally pale. The period after which reanimation may be procured is extremely various—generally from five minutes to three quarters of an hour. Of twenty-three persons recovering from drowning, one had been three quarters of an hour under water; four, half an hour; three, a quarter of an hour; and the rest for shorter periods. Dr. EDWARDS has very satisfactorily demonstrated that life is more rapidly extinguished by submersion in water of a very low temperature than in that of higher grades, evidently owing to the sedative effects of cold upon the nervous system. When submersion takes place during intoxication, there is greater risk of congestion or extravasation in the brain being superinduced; and if syncope, by the fright attending submersion, occurs, fatal congestion and paralysis of the heart and lungs will chiefly supervene, but in a slower manner than under other circumstances; and, as M. LENOIR (*Archiv. Gén. de Méd.* t. xvii. p. 469.) supposes, thus admitting of resuscitation at a longer period after submersion.

24. *B. Asphyxy from strangulation.*—When asphyxy is produced by hanging, and if the ex-

clusion of air from the lungs is complete, the following appearances are generally observed:—After loss of sensibility, epileptic convulsions, sometimes slight, at other times marked; and generally attended with erections and emissions; turgidity, suffusion, and lividity of the face, extending to the shoulders, chest, arms, and hands; the eyes are open, projecting, and their vessels injected; the features are distorted, and the tongue thrust out of the mouth; the external muscles of respiration are firmly contracted; the hands are clenched, and the sphincters relaxed. When the air is not perfectly excluded in hanging, the sufferings are prolonged, the engorgement of the head and face is greater, the lungs are less loaded with blood, and the vessels of the brain more congested, than when the air is completely excluded. In the majority of cases of asphyxy from hanging, the lungs contain more air than after death from natural causes, or from suffocation by a pillow when the air is only imperfectly excluded from the lungs.

25. There can be no doubt, that although death is caused by asphyxy in cases of strangulation, as proved by DE HAEN, MONRO, and others, the interruption which the cord occasions to the return of blood from the head, and the consequent congestion of the encephalon, accelerate death. In some instances, also, there is reason to believe that fracture, dislocation, or subluxation of the vertebrae of the neck is produced in the execution of criminals; but it very rarely, or perhaps never, occurs in cases of suicide by strangulation. To these additional effects upon the encephalon and medulla oblongata is to be partly imputed the want of success in our attempts to restore animation after strangulation.

26. *V. GENERAL TREATMENT OF ASPHYXIA.*—The indications which naturally suggest themselves from the consideration of the causes of asphyxia, their mode of operation, and the ultimate results which they produce, are, 1st, to remove the patient as soon as possible from the causes which occasioned the asphyxied state; and, 2d, to restore the function of respiration, and, through it, the circulation. The necessity of fulfilling the former of these is sufficiently obvious, and the means of doing so will necessarily vary with the nature of the cause, which should be instantly ascertained; but without delaying the employment of means to restore respiration.

27. The restoration of the function of respiration is to be attempted by various means, calculated, in the *first* place, to dislodge the impure air contained in the lungs; *secondly*, to replace it with pure air; *thirdly*, to excite the remaining vitality of the nerves and muscles; and, *fourthly*, to restore the circulation by measures calculated to return the blood from the lungs to the left side of the heart. The simultaneous attainment, as far as may be, of these objects, is to be attempted by a judicious combination of means.—*a.* The patient should be placed on his back, in an *open* air of a mild or somewhat high temperature, of from 65 to 70 deg. of Fahr., with the chest, shoulders, and head slightly elevated. He should be stripped of his clothing, and enveloped in a warm blanket. None but the assistants ought to be admitted into the room. The body should be placed at a convenient height for the employment of the measures of reanimation. *Pressure* should

then be made upon the breast and abdomen, *alternating with relaxation*, in such a manner as to simulate the actions of the chest in respiration. By this means the foul air will be thrown out of the lungs; and the restoration of the capacity of the thorax, upon the removal of the momentary pressure, by the elasticity of the costal cartilages, will draw fresh air into the lungs. It will sometimes be of service to apply a hand upon each side of the thorax below the arm-pits, and by gentle shocks endeavour to expel the vitiated air. Whilst this is being performed, bottles of warm water should be placed to the feet, under the knee-joints, between the thighs, and under the arm-pits. Dry warmth is particularly beneficial when applied to the epigastric region. Warm stimulating frictions over the surface should also be employed.

28. *b.* After having used pressure so as to simulate respiration for a few moments, *insufflation* of the lungs is next to be resorted to. This may be performed by the mouth, or by a bellows. When the latter is not at hand, the former must be adopted. The operator having closed the nostrils, and applied his mouth to that of the patient, is to blow forcibly into it, pressing the chest afterwards, in order to expel the air, and again blowing forcibly into the chest. If the lungs cannot be inflated in this way, the operator should blow into one nostril, having closed the other and the mouth; and if a small wooden tube can be procured, this may be used for the purpose, by inserting one end of it into the nostril, and blowing into the other; or the pipe of a bellows may be inserted into it.

29. *c.* *Insufflation* of the lungs by the breath of the operator has been recommended by some in preference to the use of the bellows, on account of the higher temperature of the air thrown into the lungs by the former mode; whilst others prefer the latter method, on account of the purer air furnished by it. I believe that the advantage of the higher temperature of the former nearly counterbalances the disadvantage of less purity. If, therefore, *insufflation* by the bellows of a warm air could be had recourse to, considerable benefit might be obtained. If the bellows are used, the pipe is to be introduced into one nostril; and, whilst the mouth and other nostril are closed, and the *pomum adami* pressed gently backwards and downwards by an assistant, the bellows are to be opened and immediately closed, so as to throw air into the lungs by a single stroke; after which, allowing the mouth and nostril to open, the chest is to be pressed so as to expel the air: thus air is to be forced in, and again expelled, about fifteen or sixteen times in a minute, so as to simulate respiration.

30. *d.* The *external* and *internal* use of stimulants has been recommended by J. P. FRANK and DERVIERGE. Of this class of means, *galvanism* holds the first place; but it is seldom that an apparatus can be procured. When it can be obtained, slight shocks may be directed through the diaphragm or heart: or if an electric apparatus is at hand, as strong shocks of electricity as the machine can furnish may be tried. Whilst we are proceeding with *insufflation* of the lungs, *frictions* of the surface of the body, particularly over the chest, on the insides of the thighs, &c., in order to promote the circulation and the animal heat, should be

continued; and the nostrils may be irritated, or touched occasionally with a leather dipped in spirits of hart-horn or of aromatic vinegar. Substances which are likely to increase the coldness of the surface by their evaporation should not be employed by friction. The introduction of *warm stimulating fluids* into the stomach, by means of a flexible tube and syringe, has been recommended, and may be tried after *insufflation* of the lungs has been performed for a short time. More advantage, however, will probably accrue from the administration of a clyster of warm spirits and water than from the injection of stimulants into the stomach, unless this can be done with an apparatus admitting of easy application. Tobacco-smoke has also been directed to be thrown up the rectum; but it is a more uncertain remedy than the clyster now mentioned.

31. *e.* *Bleeding* is one of the measures respecting which the greatest difference of opinion has existed. In certain circumstances it is often of great service, and in others detrimental. It is generally proper when the countenance is swollen, injected, or purplish; the veins full or distinct; and the skin reddish, or approaching the violet tint. It is not always, however, possible to obtain blood; but even when we fail in procuring it, the opening which had been made should be carefully closed and bandaged, in order to prevent subsequent hæmorrhage, which may occur when least expected. Bleeding is also often required during the progress of recovery, particularly when the respiration is laborious, the brain loaded or oppressed, and when delirium, the not infrequent attendant on restored animation, is present.

32. *f.* The means now recommended, particularly frictions, inflations of the lungs, and the occasional use of stimulants, should be persisted in for several hours, unless stiffness of the limbs, and other indications of death, present themselves. Convulsive snatches of the respiratory muscles, with gasping, followed by sighing, a more natural respiration, and slight palpitations, are the first signs of returning animation. When the circulation is restored, convulsions sometimes take place, and suddenly destroy the patient. Such seizures may occur even a considerable time after recovery has apparently been effected. The patient should therefore be watched for several days; and if an attack of this kind occur, blood-letting, and artificial respiration during its continuance, may save the patient. *Delirium*, and all the forms of morbid reaction which occasionally appear during recovery from asphyxy, require depletions, with the means usually employed to restore the secretions and excretions, and to excite the emunctories to carry off the hurtful materials accumulated in the blood during the state of asphyxy.

33. VI. TREATMENT OF PARTICULAR KINDS OF ASPHYXY. — *A.* Of *asphyxy from submersion*. But little, in addition to what has been stated above, need be adduced under this head. The body should be carried from the place of submersion to where means of restoration are to be used, in the prone posture, the head and shoulders not being elevated; but neither of them bent, or hanging in an injurious posture. The wet clothes are to be immediately removed, the mouth and nostrils cleansed, and the body placed in warm blankets; this should be done as soon as

the body is found, if the weather be cold, and the distance to the place where resuscitation is to be attempted be considerable. The directions given in preceding paragraphs (§ 27. *et seq.*), are now to be followed. Some advantage will be derived from placing the body in a warm sun, or before a fire, or surrounding it with dry warmth; heated substances may likewise be applied to the epigastrium, the extremities, and insides of the thighs. Where a warm bath can be readily procured, the body may be placed in it, and the temperature regulated to about 98° or 100°. *Animal heat*, proceeding from some of the domestic lower animals or from a healthy person placed by the side of the body, is, especially in the cases of children, a very efficacious mode of resuscitation. But all these means should not interrupt the performance of artificial respiration. The other measures recommended in the foregoing section may also be resorted to, with the exception of *bleeding*, which is seldom beneficial until the circulation has been restored; when it will not infrequently be required, to subdue morbid reaction, in conjunction with other remedies calculated to restore the secretions, &c. (§ 32.)

34. *B. Asphyxy from strangulation* requires the same measures which have been described under the head of *general treatment* (§ 26. &c.), and particularly *bleeding*, which may generally be advantageously performed in the jugular vein. The head and shoulders ought to be raised as high as may be consistent with the means used for resuscitation; and, if a restoration of animation be effected, the usual means of guarding the brain from the ill effects of reaction or congestion to which this organ is more liable after strangulation than after asphyxy from other causes, are to be put in practice.

35. In cases of asphyxy from *obstruction of the glottis and larynx*, or from substances having passed into this situation, or into the *trachea*, the operation of *tracheotomy* should be resorted to. Several instances of this description have been recorded, wherein it has been successfully performed. In all cases of recovery from asphyxy, the patient should be carefully watched for two or three days, and every appearance of reaction affecting any organ, more particularly the brain, instantly subdued by means appropriate to the circumstances of the case. Pure air, and the use of deobstruent purgatives and diuretics, are generally necessary, in order to purify the circulating fluid, and change it from the unnatural state it had assumed during the asphyxy.

1. ASPHYXY OF NEW-BORN INFANTS is frequently met with, particularly in those who are naturally feeble, or weakened by rupture of the chord or laceration of the placenta in consequence of sudden delivery, or of the operation of turning, especially when required by uterine hæmorrhage. It is also occasioned by compression of the chord, and a protracted parturition.

2. Besides the absence of respiration and of muscular motion upon delivery, the surface is pale; the flesh and limbs are soft and flaccid; the heat of the body is rapidly diminished, but the circulation still continues, at least for some time. Several cases which are viewed as *asphyxy*, more properly belong to *syncope* or *loss of blood*, or participate in those states, as well as in *privation* of the respiratory actions. This privation may depend upon imperfect circulation in the pulmonary arteries, and through the lungs; or upon inactivity of the respiratory muscles, and torpor of the nerves which supply them, owing to imperfect circulation in the brain; or upon these causes conjointly. Care should be taken to distinguish these cases from *apoplexy*; as the states of the vascular system, and of circulation in the brain, and consequently the treatment which is required in each, are very different.

3. The treatment of these cases consists of deferring the ligation of the chord for some time; of taking care that no blood is lost from dividing it; of enveloping the infant in warm flannel; of holding it near a warm fire, or plunging it in a warm bath, rendered exciting by means of salt or mustard; of removing all obstruction to the passage of air into the lungs from about the throat and mouth; warm frictions of the surface of the chest, with gentle succussion with the palm of the hand on the shoulders; tickling or irritating the nostrils and arm-pits with a feather; dropping a little diluted aromatic, or ammoniated spirit upon the lips; and most particularly inflation of the lungs by the breath of the medical attendant, either blown directly into the mouth, the nostrils being closed, and the trachea gently pressed backwards; or through a curved tube introduced into the larynx, as recommended by CHAUSSIER, and employed by him at the "*Maison d'Accouchemens*" in Paris. This latter method is certainly preferable. Insufflation is to be managed in the same manner, in other respects, as described in the foregoing article. But I think that the breath of the attendant is better suited to infants, than cold air thrown into the lungs by a bellows.

4. M. DESORMEAUX complains of his want of success from inflation of the lungs, even when carefully and assiduously employed, and places more dependence upon means calculated to excite the respiratory muscles to contract. For this purpose he recommends a species of spirit douche, and directs the practitioner to take a mouthful of brandy, and dash it forcibly against the anterior parietes of the chest. He states that this is sel-

dom required oftener than twice or thrice. Mechanical irritation of the nostrils, or exciting powders applied to the pituitary membrane, may be cautiously tried; a stimulating clyster may also be thrown up. Galvanism or electricity may likewise be resorted to when within our reach. We should not relinquish our endeavours at resuscitation under two or three hours, or even longer; and, if we ultimately succeed, the state of the infant should be carefully watched for two or three days.

1. DEFIN. *Great Difficulty of breathing, recurring in paroxysms, accompanied with a wheezing sound, sense of constriction in the thorax, anxiety, and a difficult cough, terminating in mucous expectoration.*

2. There are few diseases, the nature of which has been a subject of greater doubt and difference of opinion than asthma. Until the writings of FLOYER, WILLIS, HOFFMANN, ALBERTI, and JUNCKER, directed particular attention to its pathology, it was generally confounded with dyspnœa, being usually denominated intermittent or remittent dyspnœa. By these writers, and more recently by SAUVAGES, CULLEN, PINEL, and GEORGET, asthma was considered as essentially nervous in its nature; and the lesions found upon the dissection of fatal cases viewed as its consequences, and not as its causes. More recently, and even at the present day, among many, it has been considered as a symptom of organic change of either the heart, large blood vessels, or of the lungs, air-tubes, &c. But this doctrine, although generally accurate in respect of DYSPNŒA, is quite erroneous as applied to asthma.

3. **PHYSIOLOGY OF ASTHMA.**—The dependence of dyspnœa, not only upon organic lesions of the organs seated within the chest, but upon the form of the thorax, upon diseases of adjoining viscera, and upon the state of the air-passages, is sufficiently obvious. The difficulty of breathing proceeding from these sources may be either continued or remittent; but it never is, whilst the causes on which it depends are in existence, characterised by intervals of perfect ease. True asthma, however, presents intervals of healthy respiration; and although repeated returns of the attack will generally induce some change in the organisation of either the lungs or the principal

organs of circulation, yet this is not uniformly the case; and moreover, an attentive examination of the thoracic viscera, in recent attacks, fails of detecting in them any appreciable change, particularly during the intervals between the paroxysms. The disease has even proved rapidly fatal during the attack, and yet no alteration adequate to account for the symptoms could be detected on dissection. Instances of this description have been adduced by WICHMANN (*Hufeland's Journ.* b. i. p. 18.), PARRY, GEORGET, ÁNDRAL, LAENNEC, and GUERSENT, and justify the opinions of those who have referred the disease chiefly to the nervous system. In some cases, after repeated returns of the attack, and when they have induced organic change, the intervals are less distinctly marked, consist of remissions merely, and the disease may, at last, pass into confirmed dyspnœa.

4. A. *The structure of the air-passages and bronchi* evidently shows that these parts are susceptible of preternatural or spasmodic constriction. During 1821 and 1822, when engaged in some researches into the pathology of diseases affecting the trachea and bronchi, I was enabled distinctly to trace muscular fibres throughout those parts, both in man and in the lower animals. The disposition of those fibres, in many of the lower animals, and the mode of their connection with the cartilaginous rings, are peculiar, and beautifully adapted to guard against the contingencies to which they are liable from varying positions and habits of life. Upon those, however, I cannot here enter. About the same time that my attention was directed to this subject (*Lond. Med. Repository*, vol. xxii. p. 418.), the researches of REISSSENEN of Berlin, and of LAENNEC and CRUVEILHIER of Paris, appeared; and the results, in respect of the structure of the bronchi and larger ramifications of the trachea, upon the whole, agree with what I had observed. It had been denied that the membranous, or any other part of the air-passages contain muscular fibres. But this was asserted chiefly by those who cannot believe that a part is muscular, unless the fibres are the same in appearance as those which enter into the composition of the muscles of voluntary motion. Other anatomists, who take a more comprehensive view of the conformation and functions of the muscular system, consider, with greater justice, that the muscles which are acted upon by the will, form an order by themselves; and that there is another and a very important order of muscular parts, which are not directly influenced by volition, but which contract from stimuli acting on them, either immediately or mediately, and which present certain peculiarities in respect of the appearances of their fibres, of the mode of their distribution, and of the manner of their connection with internal tissues and organs. Now, the fibres which are discovered in the trachea, and traced to the smaller ramifications of the bronchi, are in every respect similar to other involuntary muscular fibres, in their organisation; in their connection with a mucous surface, forming, in many respects, a tunic concentrically with the mucous coat; in being disposed in circular fibres, surrounding hollow tubes; and in being supplied entirely by ganglial or involuntary nerves. The disposition of the fibres, therefore, which are detected in the air-passages, being altogether similar

to that which obtains in other canals, the muscular structure of which is not disputed, as in the alimentary tube and urinary bladder; the organisation of the fibres being also similar; their connection to a mucous surface, and the circumstance of their being supplied with the same order of nerves, being at the same time considered; are we therefore to be surprised that agents affecting either the mucous surfaces thus related to them, or the nerves supplying them, should be followed with analogous effects to those which we observe after the action of agents directed to the mucous surface or nerves of the alimentary canal?

5. *B. The lungs possess a vital power of expansion.* — The structure of the air-passages, then, would lead us, independently of the results of observation, to infer that the circular fibres are liable to experience, with all other involuntary muscular fibres, a spasmodic constriction; and it evinces, particularly in the conformation of the cartilaginous rings with which the trachea and larger ramifications of the bronchi are provided, a marked provision against an inordinate continuance or degree of this constriction; the rings, by their permanent elasticity, acting as antagonists to the circular fibres, preventing extreme constriction, and at last overcoming long-continued spasm, particularly in those larger branches, the inordinate constriction of which might have the effect of excluding the air from a very large portion of the lungs. In the larger ramifications of the bronchi, the muscular fibres connecting the extremities of the cartilaginous rings are thus antagonised by these rings; but, in the smaller ramifications, where the rings cease to be detected even in the imperfect forms in which they there exist, and where the fibres are perfectly circular, the only provision which can prevent an inordinate constriction of those fibres, is in the structure of the lungs themselves, which must necessarily undergo a change in bulk, and become more condensed by this constriction, in those parts, at least, to which the spasm extends; unless we believe that the lungs, like various other organs, are endowed with an expansive power. — a power which physiologists and pathologists have too much overlooked in their exposition of the healthy and morbid actions of the animal economy.*

6. The mechanism of the expansive power is so little understood, and generally so insufficient for the explanation of this phenomenon, that we must refer chiefly to the vital actions of the part, which must necessarily depend on the energies of the body generally. The expansile action of the penis, nipple, heart, uterus, &c. cannot be explained by their organisation only: it is manifested to us only during life, and the perfection as well as imperfection of this action are always accordant with the degree of vital energy with which these organs are endowed.

7. I have long since had occasion to remark that the motions and functions of the lungs (*Phy-*

siological Notes, &c. to M. RICHERAND'S *Physiology*, 2d ed. p. 628.) have been too generally and exclusively referred to the mechanism of the respiratory organs, and to chemical changes produced in the lungs, to the neglect of a much higher influence, always controlling, modifying, or altogether changing, the subordinate powers to which their functions have been thus referred. That the vital energies of the frame are most powerfully exerted in the lungs, through the medium, especially of the organic nerves with which they are provided, must be evident to all who will contemplate the nature and extent of the changes constantly taking place in these organs upon the blood circulating through them; and the relation which subsists between their functions and the vital energies of the system generally. Now, it does appear to me that there exists a vital expansion of the lungs independent of that which they experience from atmospheric pressure, and from following the dilated parietes of the thorax during inspiration. In experiments upon living animals, where the walls of the chest have been opened, the lungs are observed to swell and contract alternately. This fact, which was first insisted upon by M. ROUX (*Mélanges de Chirurgie*, p. 87.), has since been duly appreciated by PRUS, LAENNEC, and a few others. Even in cases where the portion of lung has protruded itself after a wound of the chest, — a circumstance which could only occur from active expansion of the lung itself, — this portion has been, although thus unnaturally placed and subjected to the pressure of the atmosphere, observed to dilate during inspiration. The not infrequent occurrence of ossification of the cartilages of the ribs in old persons, and consequent perfect immobility of the ribs, even without any evident dyspnoea, furnishes another proof of the inherent expansibility of the lungs: for without having recourse to this vital property, we cannot explain the performance of the actions of inspiration and expiration by the diaphragm alone.

8. This vital property, therefore, with which the lungs, in common with some other organs, seem to be endowed, together with the disposition and elasticity of the cartilaginous rings of the bronchi, furnishes an antagonising force to the unnatural constriction of the tubes from spasm of their circular fibres; and, while it serves to explain the natural functions of the organ, with their modifications from the various influences to which this property is subjected, is one of the sources to which we are to impute some of the diseases, and more especially the one under consideration, to which the lungs are liable.

9. Having thus shown, from the structure of the air-passages, that they, in common with all other hollow tubes of the body, admit of spasmodic constriction, and that they also present a provision against the undue extent or continuance of this state, I should further remark, that a close observation of the phenomena of disordered respiration is sufficient to convince us that they frequently experience this state owing to the operation of certain causes acting either directly on the mucous surface of the tubes, and impressing the nerves terminating in it, or originating in and irritating the nerves themselves, either at their origins or in their ramifications and connections.

* That the lungs, however, really possess this property, may be inferred from the permanent elasticity of their structure, which continues for some time after death; and which is still more marked during life, as shown by exposing the lungs of a living animal. This state may be with propriety called the vital expansibility of the lungs, inasmuch as the degree of this state is chiefly dependent upon the vital energy of the system, and partly on the peculiar organisation of the lungs themselves.

10. I. SYMPTOMS AND HISTORY OF ASTHMA.—The *premonitory* symptoms of this disease are languor, sickness, flatulency, and other dyspeptic disorders; heaviness over the eyes, and headach; uneasiness and anxiety about the *præcordia*, with a sense of fulness and straightness in this region and in the *epigastrium*. In some cases pain is complained of in the neck, with uncommon drowsiness and stupor. It is also often preceded by costiveness and inefficient calls to stool.

11. *A.* The *invasion* of the attack of *spasmodic asthma* is generally soon after midnight, or about one or two in the morning, and during the first sleep. The patient wakes suddenly from a sense of suffocation. He feels a most distressing tightness at his chest, with great anxiety, difficulty of breathing, and impediment to the free admission of air into the lungs. He assumes with eagerness the erect posture, and cannot bear the least incumbrance about the chest. The breathing is wheezing, interrupted, and laborious. The shoulders are raised, the elbows directed backwards, and every effort made to enlarge the thorax. Owing to the interrupted circulation through the lungs and heart, the countenance, which was at first pale and anxious, becomes, particularly in plethoric habits, red or bloated, and covered with perspiration. The eyes are prominent, and the conjunctiva injected. A considerable quantity of pale urine is usually passed at the commencement, or previous to the accession, of the paroxysm; and the lower extremities are usually cold. The pulse is generally accelerated, weak, irregular, and often intermittent. During the fit, the patient has commonly an instinctive desire for cool fresh air, which always revives him. A small or close room is offensive, and all warm substances given internally increase the flatulency of the stomach and bowels, and aggravate the symptoms. When the fit has continued from half an hour to one, two, three, or even four hours, it leaves the patient; and his respiration, pulse, and feelings assume their natural state.

12. This is the common course of a first and moderate attack of the disorder. Sometimes the patient has but one such fit; but more generally a slight constriction of the chest is felt through all the succeeding day, and the paroxysm returns at the usual period of the night; and this continues for three, four, or even seven days; when the patient is at last altogether relieved from the attack. The disease may be suspended for a month, or several months; but it is liable to recur from changes of air, errors of diet, and from the operation of the other causes productive of it.

13. In some cases the attack is more severe from the commencement, and continues, with slight remissions, for several days, accompanied with a harsh suffocative cough, great distension of the abdomen from flatus, and more or less of the symptoms which characterise the complaint in the severer states resulting from repeated attacks.

14. When asthma once seizes on the system, it seldom fails of recurring, though the intervals between the paroxysms are of very uncertain duration. In many cases it recurs periodically every ten days or a fortnight. Sometimes the attack returns at the full and change of the moon, or at one of those periods only. It has been observed to recur in females just after the menstrual discharge, or to precede this evacuation. Persons

who have become subject to the disease seldom escape an attack in the spring and autumn.

15. After repeated seizures, the disease often assumes the most violent and distressing features; the difficulty of breathing in the fit amounts to the utmost degree, and is attended with the greatest tightness over the whole chest, the patient feeling as if he were bound with cords. His anxiety at this period is inexpressible, and he labours in respiration as if every moment would be his last. Severe vomiting also frequently occurs. The matter discharged is slimy and frothy, or of a greenish yellow colour. He is subject to palpitations and faintness; and cool fresh air becomes absolutely necessary. About this period a loose stool sometimes takes place. The eyes are prominent, the face sometimes pale, sometimes high-coloured, bloated, or livid: the nose and ears are cold: the face, neck, and chest, covered with perspiration. The pulse is generally extremely weak, irregular, and even intermitting; there is often much difficulty of swallowing. The patient can scarcely speak, cough, or expectorate, and the stomach and bowels are much distended with flatus. As the paroxysm abates, the cough becomes freer, and is attended with the expectoration of a little viscid mucus; and, in proportion as the cough and expectoration increase, the distressing symptoms abate; this evacuation, which had been retained by the spasm of the air-vessels, indicating a solution of the spasm and a freer access of air to the cells of the lungs. An easy and free expectoration, particularly if it be accompanied with softness and moisture of the skin, and a sediment in the urine, is a certain indication of the subsidence of the attack. Sometimes when the paroxysm is unusually long, the patient experiences only a single occurrence of it during the attack.

16. *B.* The *Humoral* form of asthma is generally gradual in its accession, and attended by extreme oppression, a suffocative cough, and a copious secretion and expectoration of mucus from the commencement of the seizure (§ 11.). It is sometimes the consequence of repeated attacks of the preceding variety; and is generally more severe and of longer duration than it, owing to the accumulation of viscid mucus in the air-vessels conspiring with the spasm it occasions to aggravate the symptoms. There are also less perfect intervals of ease in this form of the malady, than in the spasmodic. After the subsidence of the patient's sufferings during the first night of the attack, and while the expectoration is easy and copious, the lungs still continue irritable through the day, and the respiratory function embarrassed from the slightest causes. At the approach of night, the fit recommences with the usual symptoms, and the night is passed nearly as the former. On the third day the remission is more complete, there is some additional expectoration, and bodily motion is performed with less distress, but still with great inconvenience. After the paroxysm has been renewed in this manner for three or four nights, or for a longer period, sometimes for several days or even weeks,—for the duration of an attack varies much,—the expectoration and cough are more easy and free, the daily remissions become more perfect, and the strength of pulse and vigour of action increase.

17. When the chest is examined by the ear or

stethoscope, the sound of respiration is weaker during the fits than in the intervals, but it is seldom altogether suspended in certain points of the chest; it is attended by a sonorous rattle, flat or sibilous, imitating the chirping of birds, the note of a violoncello, or the cooing of a wood-pigeon. With this there is frequently intermixed a mucous rattle; but this conveys the impression of being produced by a thinner fluid than the mucus of common catarrh. In the intervals of the attack, these various species of rattle exist, but in a much less degree. The respiratory sound is louder than during the paroxysms; sometimes it is almost puerile. If the complaint have occasioned dilatation of the bronchi, the respiration assumes more or less the character of the variety called bronchial; in all cases it varies in intensity at different points of the chest, and these points change their situations from day to day (LAENNEC). The chest generally sounds well, throughout the attack, upon percussion.

18. I have stated (§ 16.), that the humoral form of asthma is often consequent upon repeated attacks of the spasmodic; but this latter may also occur, although rarely, after the former; or the attacks in some persons present an evident complication of both forms of the disease. The stomach and bowels are extremely liable to disorder in asthmatic persons, particularly in those subject to the spasmodic form of the disease. Colic pains, flatulence, loss of appetite, an irregular state of the bowels, and a disturbed, impaired, and unrefreshing sleep, generally harass the asthmatic patient, even in the intervals between the seizures. In females, the menses are generally impaired or irregular, and an attack often precedes the period of the menstrual discharge, the supervention of which generally acts as a crisis of the attack.

19. Symptoms of fever are not essential to the disease, though they often occur, especially when the humoral asthma, or an attack of catarrh, is complicated with the convulsive. Hectic fever, colliquative diarrhoea, faintings, palpitations, vomitings, coldness of the extremities, swelled legs, and other dropsical symptoms, are common in the last stage of the disease, and indicate organic changes in the substance of the lungs or heart, with obstruction to the circulation in these organs, and effusion of fluid in the chest,—results, however, which can only be ascertained with precision by means of auscultation and percussion.

20. *C. Terminations.*—An attack of asthma generally terminates in one of three ways: 1st, By a return to the healthy function: 2d, By inducing further lesion; in which it either disappears, or becomes complicated: and, 3d, In death. On each of these I shall offer a few remarks.

21. *a.* Although the paroxysms of asthma frequently terminate in a return to the healthy functions, a perfect immunity from future attacks can rarely be procured. Yet these attacks may be frequent, severe, and of long duration, recurring for a long series of years; the patient, notwithstanding, arriving at a very advanced age, before a fatal issue takes place. But they often produce the following organic lesions.

22. *b.* The most common consequences of the disease to which I may now advert, are chronic inflammation and dilatation of the bronchi; the different forms of emphysema and œdema of

the lungs; hæmoptysis; tubercular formations, with which asthma may also be associated from its commencement; enlargement, and dilatation, &c. of the cavities of the heart; effusions of fluid in the pleura or pericardium; and wasting of the heart, or polyposus concretions, within its cavities. As the reader will find all those lesions treated of under their distinctive heads, I shall here only remark respecting them, that, when they supervene to asthma, many of the distinctive characters of this disorder entirely disappear in those of the superinduced disease, and the lesions of the respiratory functions assume the distinctive features of chronic, continued, or remittent dyspnoea. Severe attacks of asthma may also terminate in congestions or effusions within the head, giving rise either to epilepsy, coma, or apoplexy.

23. It was already remarked, that auscultation and percussion furnished merely negative information in the different forms of asthma. But this information is still important, inasmuch as it intimates the non-existence of any of the foregoing organic changes; and when they do exist, those means of diagnosis enable us not only to recognise them, but also to ascertain with precision their nature, progress, and extent, and thus to form an accurate diagnosis and prognosis in respect both of the primary disease and of the consecutive organic changes.

24. *c.* When the disease ends in death, this event is brought about generally by superinducing some one of those changes already referred to as terminations of the disease, or of those lesions, with which it is frequently associated (§ 22.). Death may, however, occur, but much more rarely, from the severity of the attack; the requisite changes not being effected on the blood by respiration, owing to the obstructed state of the air-vessels, either from spasm or the accumulation of viscid mucus, or from both, whereby the nervous centres are supplied with blood unsuitable to their functions, and the heart ceases to contract with sufficient energy to preserve the circulation in a requisite state of activity through the lungs and brain.

25. *D. The appearances after death* may be inferred from what has already been stated. These appearances are rather the consequences of the disease, than the disease itself; for it is seldom that we have an opportunity of examining the body in recent and uncomplicated cases of asthma. Where, however, this has been done, the lesions, even when any have been detected, have been insufficient to account for the disease. WILLIS records a case of protracted asthma, in which no morbid appearance could be detected; and similar cases have occurred to LAENNEC, ANDRAL, CRUVEILLIER, BOULLAUD, JOLLY, and others. FERRUS, after extensive experience, states that he has been unable to detect any lesions which can be attributed to uncomplicated asthma. The changes which have been noticed, therefore, by authors, are to be viewed chiefly as accidental occurrences, or associated maladies; and, perhaps, more frequently as the remote results of repeated or protracted attacks. The appearances usually observed in fatal cases are the same as have been described (§ 22.).

25. II. *VARIETIES OF ASTHMA, AND OF THEIR PATHOLOGY.*—SAUVAGES has enunciated no less

than eighteen forms of this disease, many of them presenting no modification of the phenomena constituting the disease, but merely peculiarities as to cause, particularly as respects the occasional causes. Several of his varieties, also, strictly belong to the more generally symptomatic complaint to which the term *DYSPNŒA* is usually applied. The varieties of idiopathic asthma, according to CULLEN, are the *SPONTANEOUS*, *EXANTHEMATIC*, and *PLETHORIC*. Dr. BREE, who has given a comprehensive account of the disease, has divided it into forms which have reference chiefly to the doctrine which he has espoused respecting its pathology. He assigns to it four species:—1st, Asthma produced by the irritation of effused serum in the lungs; being its most common form: 2d, That occasioned by the irritation of aerial acrimony in the lungs; 3d, That dependent on irritation in the stomach, or some of the abdominal viscera: and, 4th, That dependent upon habit. Dr. YOUNG has adopted a similar arrangement.

26. M. LAENNEC has given a simpler view of the disease, and assigns it two forms, viz. asthma attended with *puerile respiration*, in which the vital expansibility of the lungs is increased, from a temporary augmentation of the want of the system for respiration, occasioned by some unknown modification of the nervous influence; and *spasmodic asthma*, from a spasmodic constriction of the air-tubes. Dr. GOOD has divided the disease into the *dry* and *humid*; but he has encumbered these two species with nearly as many varieties as have been assigned by SAUVAGES. The *dry* or *nervous* asthma he subdivides into the simple, metastatic, phlegmatic, vaporose, and organic,—a refinement which is neither founded in nature, nor can be available in practice; for a simple nervous asthma may be induced by injurious vapours, or by repelled eruptions, and hence we have the first variety produced by either his second or fourth; and the second, or the phlegmatic nervous asthma, may proceed from the same varieties. His fifth variety is certainly not admissible under asthma, unless as a consequence of the disease, but falls more properly under dyspnœa, either in its continued or remittent forms. The *humid* or *common* asthma he subdivides into the simple, plethoric, and atonic,—a division much more accurate than the foregoing, but still objectionable, inasmuch as it is impossible to draw any line of demarcation between them, and as the three varieties insensibly pass into one another.

27. By the great majority of authors who have written on the disease, it has been viewed simply in respect of its *IDIOPATHIC* and *SYMPTOMATIC* forms; both, however, presenting modifications resulting from peculiarity of causes, and the circumstances of the patient, but insufficiently marked to constitute distinct varieties. In the following observations I shall observe the same distinction, and divide the *IDIOPATHIC* FORM of the disease into, 1st, The *nervous* asthma; 2dly, The *primarily spasmodic* asthma; and, 3dly, The *pituitous* or *humid* asthma.

28. 1st, *Nervous Asthma*. The asthma with puerile respiration, *Laennec*. — *CHAR.* *Anhelation from a feeling of want of a more complete respiration than the patient enjoys, the pulmonary expansion distinctly taking place with promptitude,*

completeness, and uniformity, so as to furnish a general puerile sound on auscultation; usually accompanied with a slight cough, and with a free mucous expectoration.

29. This form of the disease was first accurately described by LAENNEC, who pointed out the difference between it and the forms depending on spasm of the air-tubes. In this variety no spasm seems to exist in the smaller air-vessels and cells: for the whole tissue of the lungs is dilated to its full capacity, and with unusual promptitude and completeness, so that the puerile respiration is heard in every part of the chest; whereas in the other varieties the respiration is generally somewhat more indistinct than in health. M. LAENNEC contends, and apparently with justice, that the wants of the system, in respect of respiration, may be exactly measured by the intensity of the respiratory sound; and that the intensity varies much, according to many circumstances, and particularly according to the age of the individual, it being much greater in childhood than in adult life. There is no morbid affection, he observes, which can be more satisfactorily referred to simple disorder of the nervous influence, than this dyspnœa accompanied with puerile respiration. In cases of this kind, the respiratory sound has resumed all the intensity which it possessed in early life. The pulmonary expansion evidently takes place completely and rapidly in all the air-cells, and yet the patient feels the want of a more extensive respiration than he enjoys; and the lungs, although dilated to their utmost, have not, nevertheless, capacity enough to satisfy the wants of the system. This affection is common in persons affected with chronic mucous catarrhs, attended by a copious and easy expectoration; but even in them, during the severest attacks, the completeness with which respiration is performed is quite astonishing. Nevertheless the patient feels oppressed, and requires a more extensive respiration than his organisation allows; the wants of the system in respect of this function being increased beyond the standard of health.

30. In this form of the disease it is not in the small air-tubes that we are to look for its proximate cause, but in the trachea and large bronchial trunks, and particularly in the nervous influence itself; and this will equally hold good even if we adopt the chemical theory of respiration, and refer the affection to an extraordinary want of oxygen in the blood, arising from impeded function of the respiratory mucous surface, owing to the mucous secretion covering it. M. LAENNEC believes, as this species occurs only in persons affected with chronic mucous catarrh, that it can never amount to asthma, without the catarrhal complication. Adults and old persons, he remarks, who have puerile respiration without catarrh, are not, properly speaking, asthmatic; but they are short-breathed, and dyspnœa is induced by the slightest exertion, though when sitting still they frequently experience no oppression whatever.

31. This variety may be considered as depending upon a temporary augmentation of the want of the system for respiration, occasioned most probably by some unknown modification of the nervous influence; and apparently consisting in an expansile action of the lungs increased much beyond the healthy standard. But here a ques-

tion suggests itself, viz. can this augmented action of the lungs be owing solely to the state of this organ, or is it associated with, or partly depending upon, increased activity of the respiratory muscles, particularly the diaphragm? M. LAENNEC states that it cannot be produced at will by a full inspiration; and, therefore, infers that this state of the lungs is a primary condition of them, and not depending on increased inspiratory efforts.

32. From this consideration I am led to infer that, although the vital expansile action of the lungs may be increased in this variety of asthma, it is accomplished with, and much assisted by, augmented activity of the diaphragm, which performs its office more promptly and completely in this variety of asthma than in any other; that instead of the disease being characterised by spasm of the smaller ramifications of the bronchi and air-cells, as in the second variety of asthma, the air penetrates more fully into them than usual; and that, if any spasm exists, it is limited to the trachea and large bronchial tubes; the exalted state of expansion of the lungs, and of function of the diaphragm, being an effort to counteract this morbid condition of the large tubes, and to supply the wants of the system by a more forcible inspiration; the increased rapidity with which the air is thereby made to pass through the strictured canals making more than amends for the diminished calibre of the passage. This form of the disease is frequently *symptomatic* of nervous affections, particularly of hysteria, when the globus hystericus affects the state of the trachea, and of various diseases, in which the blood is imperfectly changed in its circulation through the lungs. But when thus symptomatic, it is often slight and evanescent.

33. 2d, *Spasmodic Asthma*. SYN. *Periodic Asthma*. *Convulsive Asthma*, *Willis*, *Baglivi*, *Boerhaave*. *Asthma Siccum*, *Musgrave*. *Occult dry Asthma*, *Etmuller*. *Spasmodic Asthma*, *Laennec*. *Dry Asthma*, *Good*. — CHAR. *Paroxysms sudden, violent, and of short duration, attended with hard spasmodic constriction in the chest; slight, dry, and difficult cough, and with a scanty expectoration, occurring only towards their close*.

34. I stated that the vital expansive action of the lungs was increased in the foregoing variety. In this the ramifications of the air-tubes, and perhaps the air-cells themselves, seem to be unnaturally constricted. The respiration, when examined by the stethoscope, or by the ear merely, is heard either very imperfectly even on the most forcible respiration, or to a small extent only, or its sound may be but little impaired. The chest, during the paroxysm, sounds ill on percussion. These phenomena indicate that there is an imperfect entrance of the air into the air-cells. M. LAENNEC states, that if the patient after holding his breath nearly as long as he can, breathes quietly, the spasm will often be overcome as it were by surprise, and the entry of the air into the cells will be heard in a clear or even puerile sound. This, and various other circumstances, independently of the proof furnished by the structure of the air-tubes, indicate that the obstruction to the entrance of air into the cells is owing to spasm of the muscular fibres.

35. Dr. WILLIAMS believes that spasmodic

asthma may be partial, affecting one lung only, or one more than the other; but this is very seldom the case, unless when it is occasioned by, or complicated with, dry catarrh, which is sometimes partial; or when the spasmodic constriction is excited by a collection of a pituitous fluid in some of the bronchi,—a complication of not infrequent occurrence, but falling more strictly under the next form of the disease. Although the paroxysms of the primarily spasmodic asthma are sudden, and generally of short duration, yet the disease is often of long continuance, and may, to a certain extent, become habitual, as shown by Dr. BREE and others.

36. During the spasm, the lungs seem, from an attentive examination of the thorax, somewhat drawn together, owing to the constriction of the air-tubes; and the parietes of the chest, being necessarily pressed inwards at the same time, generally yield a less clear sound on percussion. The *scrobiculis cordis* is also drawn inwards and upwards, indicating the manner in which the diaphragm is affected during the paroxysm. This phenomenon, which was first pointed out by SCHEIDMANTEL (*Fränkische Beiträge*, No. 5.), arises either from the diaphragm being prevented from contracting to its full extent by the spastic constriction of the air-vessels, or from a temporary paralysis of this muscle. That the latter state should take place, and be followed in a short space of time by a perfect restoration of action, and that repeated seizures of this description should be always succeeded by a similarly rapid return to the healthy state, cannot be admitted by any person who takes an intimate and comprehensive view of the operation of the animal economy in health and disease. That retraction of the epigastrium, and even of the hypochondria, is owing to imperfect descent of the diaphragm from constriction of the air-cells, seems proved by the circumstance, that the pleural cavity is perfectly closed, and forms nearly a vacuum, and consequently the capacity of the thorax cannot be enlarged by the action either of the diaphragm or of the other respiratory muscles, without the expansion of the lungs. But this organ is only imperfectly expanded, owing to the spasm of its air-vessels; consequently the diaphragm either cannot assume its usual place, or does so imperfectly, notwithstanding its efforts to accomplish this end; and the parietes of the thorax are every where pressed inwards, following the retracted state of the lungs themselves, and are only partially dilated after the most energetic action of the respiratory muscles, which at last overcomes the spasm of the air-tubes, as the want of respiration throws the former into spasmodic action, and tends to relax the spastic state of the latter.

37. This condition of the air-vessels, and the antagonising action of the respiratory muscles during the paroxysm, have a necessary tendency to form a vacuum in the thoracic cavity; but this can take place to a very small extent only, as the action of the respiratory muscles is insufficient to overcome both the pressure of the atmosphere surrounding the chest, and the spastic stricture of the air-tubes, as long as this stricture continues in full force. The consequence, however, of this antagonising action and tendency to form a vacuum is, that a larger quantity of blood is

drawn into the large veins within the thorax, and into the venous sinuses and auricles of the heart, occasioning congestion of those cavities, impeding circulation through the lungs, congestion within the head, and inordinate and irregular action of the heart, with various other injurious effects upon the central organs of circulation, as well as upon the cerebro-spinal centres.

38. In addition, also, to these effects, which take place during the antagonising struggle characterising the paroxysm, rupture of one or more of the air-vessels or cells sometimes takes place, in consequence of the violent action of the inspiratory muscles on the one hand, and the unyielding state of constriction of the air-vessels on the other (§ 136.); and emphysema of the lungs is superinduced, forming one of the most common lesions found upon dissection of fatal cases, and in the opinion of some pathologists the proximate cause of the disease. (See LUNGS, *Emphysema of*.)

39. 3d, *Common or Humid Asthma*.—*SYN.* Catarrhal Asthma; Continued Asthma; Humoral Asthma; Ptituitous Asthma. Spitting Asthma, *Floyer*. Asthma Humidum, *Riverius* and *Musgrave*. A. Pneumaticum, *Willis*. A. Humidum, *Bugliui*. Ptituitous Catarrh, *Laennec*.—*CHAR.* *Gradual accession of the paroxysms, which increase in severity, are protracted, and attended with heavy and laborious constriction of the thorax, severe suffocative cough, and with expectoration, often commencing early, at first viscid and scanty, but becoming copious and affording relief.*

40. This common form of asthma may present various pathological states and relations. It may, as stated by *CULLEN* and *GOOD*, be characterised by *plethora* of the vascular system generally, and of the pulmonary tissue especially, particularly when it supervenes to the suppression of some accustomed evacuation. It may also be associated with a relaxed or *atonic* state of the exhalants of the bronchial surface, particularly when it takes place after chronic catarrhs, and in aged or phlegmatic subjects; and it may be attended with both these states, namely, with *plethora* of the sanguineous system, and atony of the exhalent pores of the respiratory mucous surface. Besides these states, it may vary in the acuteness and chronicity of its symptoms and progress; it being either *acute* or *chronic*, or presenting grades intermediate between both.

41. The chief characteristic of this variety of asthma is the copious discharge of viscid mucus accompanying it. But the questions with several modern pathologists have been, whether the phenomena of the disease are to be imputed solely to the accumulation of this fluid in the air-passages, or in part only; and whether the spasm of those passages also exist in conjunction with an increased secretion of mucus, or not. I believe that an attentive observation of the phenomena of the disease, with the assistance of auscultation and percussion,—which, however, occasionally furnish but little information, and that of a negative description, in this disease,—will lead to the inference that it depends upon both those morbid states. The limits of our inquiry are now narrowed to the question of the priority of their existence, and the relation which the one holds to the other. As to these points it may be remarked, that the early occurrence of expectoration, as well as its abundance, forbid the inference that the production of

viscid mucus is the consequence of relaxation of the spasm; whilst they favour the idea that the spasm is occasioned by this secretion in the irritable and morbid air-tubes; the severity and duration of the paroxysms being occasioned by these double states of disease,—an abundant secretion of viscid mucus in, and a spastic constriction of, the air-passages.

42. But it may be further inquired, are not those morbid changes the effect merely of a certain condition of the air-passages still more intimately connected with the disease than they are? I do not deny the possibility of lesions antecedent to those now specified; but the difficulty of ascertaining their exact nature must be conceded. It would certainly be advantageous to obtain this information, inasmuch as on it would be based the means of cure which might be employed early in the disease. That it is not inflammation is proved by concomitant and symptomatic phenomena, by the course of the paroxysms and of the disease, by the terminations usually characterising it, and by observation of the *juvantia* and *ladantia* during its progress. It seems, however, extremely probable that the morbidly increased secretion and spasm are preceded by a congestive state of the mucous respiratory surface; this state disposing to the spasm, and being, as well as the spasm itself, at last relieved by the copious effusion of mucus; the mucus first effused tending, however, for a time, to increase the spastic constriction of the air-passages, and the consequent struggle of the respiratory muscles to overcome it (§§ 36, 37.), and to procure a fresh supply of air in the lungs. This antecedent state of vascular turgescence of the mucous surface of the bronchi in asthma, is perhaps most marked in that form of this variety, in which little or no expectoration accompanies the cough, at least early in the attack, and which, from this circumstance, and the causes which induce it, has been called the *dry catarrhal asthma*.

43. If it be still further asked to what cause are we to impute this congestive state of the respiratory surfaces? I can only answer, to a certain primary change of the vital energy of the organic nerves supplying the blood-vessels, and actuating the muscular fibres of the bronchi; and hence, as the morbid changes of the circulation, secretion, and calibre of the air-passages, are merely effects of one cause,—of a previous change of the vital manifestations of the nerves of the organ,—it becomes of the utmost importance to ascertain the nature of this primary change with as much accuracy as possible, in order that remedial agents may be directed with precision to its removal; but the prosecution of this very interesting topic falls under another division of my subject. In estimating, however, the nature of this, as well as the other varieties of asthma, the difficulties opposed to expiration by the spasm of the air-tubes, and the accumulation of viscid mucus in them, have been too generally overlooked in our eagerness to ascribe all the morbid phenomena to impeded inspiration. But I believe that the disease, particularly this variety of it, is as much occasioned by the obstacle these states of the air-passages present to free expiration; the air, by the greater power of the inspiratory over the expiratory muscles, being drawn in sufficient abundance into the lungs,

from which it is imperfectly expelled. From this circumstance the lungs are often kept in a state of inordinate dilatation, and the respiratory muscles excited to convulsive actions, occasioning dilatation or rupture of the air-cells, and consequent emphysema of the lungs. In the more advanced stages of the disease, in old and debilitated subjects, this struggle to dilate the thorax still further, proceeding from the wants of the system for respiration, and to expel the air from the lungs through the obstacles placed in its way, generally terminates unfavourably to the latter part of the respiratory actions; consequently expectoration is impeded or suppressed, and life is terminated, with the air-tubes and cells, and even the substance of the lungs, loaded and infiltrated with mucus, air, and serum. It is in this state that active stimulants and emetics, by rousing the energies of the frame, and by exciting the expiratory efforts during the process of vomiting, prove so frequently beneficial.

44. This form of asthma may be partial, affecting one lung only, or one more than another; but it is more commonly general; and in some constitutions, particularly in aged persons, and when it has supervened to repeated attacks of catarrh, the quantity of viscid mucus expectorated is very great.

45. Its *anatomical characters* are, slight swelling, or thickening, and softening of, the mucous membrane, with a slight appearance of redness in parts, and with marked congestion, and purplish tint of portions of this surface in the more severe or protracted cases. Sometimes these lesions are accompanied with slight œdema of the membrane, and the development of miliary tubercles in the lungs.

46. As the majority of cases of this disease is characterised from the commencement by copious expectoration, it becomes a question how far it deserves to be considered as a variety of asthma; but taking all its phenomena into consideration, particularly the spasm of the air-passages, and convulsive action of the respiratory muscles, as well as the circumstance of its having been usually considered as a species of asthma, and the difficulty of arranging it otherwise, I was unwilling either to assign it a different place, or to make it a distinct disease, to which it scarcely can lay claim. M. LAENNEC has placed it amongst catarrhal inflammatory affections of the bronchi; but I conceive that it is seldom inflammatory either in its origin or progress; and that, although occasionally commencing in, and always aggravated by, catarrh, it is not necessarily a catarrhal disease. Besides, inflammations of the bronchi and catarrhs are not identical affections, although the latter frequently pass into the former.

47. But, besides these considerations, many of the phenomena essentially characteristic of asthma always attend it to a greater or less extent. Upon an attentive examination, however, of the chest of a person afflicted with this affection, by auscultation and percussion, these phenomena are found to vary, in different cases, or even in the same case, at different periods of the attack; yet they are essentially the same as those which mark the preceding varieties, although not so evident to the senses as in them, inasmuch as they are obscured by a more prominent symptom—the copious mucous secretion and expectoration. Sometimes it

is manifest that certain parts of the air-tubes are differently, or even oppositely, affected at different periods of the attack. When the viscid mucous secretion proceeds from, and is still present in, the smaller ramifications of the air-vessels, this condition, together with some degree of spastic constriction of their circular fibres, either in a part only, or more or less throughout the organ, occasions many of the symptoms which characterise the *second* or spasmodic variety of the disease. But in proportion as the secretion rises to the larger air-tubes, and leaves the smaller ramifications clear; or when the mucous secretion proceeds chiefly from the former parts, and excites, or is accompanied with, spasms of these canals, but not to the extent of preventing the passage of air into the parts of the lungs which they supply; these parts generally expand freely, owing to the vital activity of the organ, the wants of the system for the changes effected on the blood by respiration, and the active contraction of the inspiratory muscles during the convulsive efforts of the paroxysm. Hence the part of the lungs thus affected generally furnish the puerile respiration, and a clear sound on percussion, with a full and prompt performance of the inspiratory actions,—phenomena characteristic of the *first* or nervous form of asthma.

48. III. DIAGNOSIS.—From the foregoing account of the symptoms and forms of asthma, it will appear obvious that the distinction of it from every other disease cannot be difficult, particularly if we carefully bring auscultation and percussion to our assistance. The sudden attack of the paroxysms, the short period of their duration, the violence of their symptoms, their returning after intervals of ease and of tolerable health, are sufficient to characterise the disease. It is only when asthma is complicated with, or has induced, other diseases—as chronic or acute bronchitis, pneumonia, tubercular phthisis, organic changes of the heart and large vessels, or effusions of fluid within the thorax—that difficulty can arise in determining the exact state of parts; and here we have it in our power to resort to auscultation and percussion, which, if this disease be simple and uncomplicated, will furnish us with no very unnatural sound, at least with none which will exist with any permanency in any particular part of the chest; and if it be complicated, the nature and the extent of the organic changes will be ascertained by these means, as pointed out under their respective heads.

49. *A. Spasmodic affections of the larynx* may be mistaken for asthma; but they may readily be distinguished from it by the sound occasioned by the passage of air through the narrowed passage, which is very different from the wheezing sound of the asthmatic respiration. Besides, in all the affections of the glottis, the patient readily points to it as the seat of his sufferings. The patient also betrays much more alarm of impending suffocation; whereas in asthma he is seldom apprehensive of the result, however severe the attack may be.

50. *B. Severe cases of acute bronchitis*, owing to the viscid and copious expectoration accumulated in the bronchi and trachea, and to the spasm excited in these parts and in the glottis during its expulsion, are often accompanied with fits of

difficult and spasmodic respiration, so severe as to approach nearly to the character of the asthmatic paroxysm. But the presence of inflammatory fever in bronchitis; and the copious, albuminous, thick, and glutinous expectoration; the absence of the distressing sense of stricture of the chest and dyspnoea which attend asthma; the gradual accession and increase of bronchitis; its continued character, and slow subsidence; and the varying appearance of the expectoration, with the different stages of the disease; will be sufficient to distinguish it from the humoral form of asthma, unless both affections are associated, or the one passes into the other, which sometimes occurs, as when bronchitis seizes the asthmatic subject.

51. *C. Angina pectoris* may also be mistaken for a severe fit of asthma. But the circumstances inducing an attack of both affections, and the periods of their accession, are different. Besides, the fit of angina pectoris is attended with a feeling of impending dissolution—a sensation which never accompanies the asthmatic paroxysm. The peculiar pains, also, under the sternum, and pain and numbness of the left shoulder, arm, &c., characterising the former, are not present in the latter affection. When asthma becomes associated with *disease of the heart and large vessels*, these sensations may accompany it, which will render the diagnosis more difficult. But still the accession of the asthmatic fit in the evening or night; the comparative immunity from it during the day, and in the open air; the history of the case; and the antecedent or attendant disturbance of the gastric functions; will still continue, and serve to point out the nature of the disease.

52. *D. Hydrothorax* is frequently attended with suffocating paroxysms of difficulty of breathing occurring during the night. But it may readily be distinguished from asthma by the scanty urine; by external œdema, particularly of the extremities; and the dead sound furnished by percussion, and the absence of the respiratory murmur. It must not, however, be forgotten, that hydrothorax is not infrequently consecutive of chronic asthma, particularly when the valves and cavities of the heart have become diseased in the course of the asthmatic attacks.—The affection denominated the *Acute Asthma of Infants*, by MILLAR; *False Croup*, by GUERSENT; and the *Spasmodic Croup*, by WICHMANN, MICHAËLS, DOUBLE, &c., is nearly allied to spasmodic asthma; one of the chief differences being its occurrence in infants. Its diagnosis, &c., will be found in the article on *CROUP—Spasmodic*. The practitioner should also be careful not to confound the disease with the difficulty of breathing which sometimes accompanies hysteria, hypochondriasis, and the passage of foreign bodies into the trachea.

53. IV. PROGNOSIS.—There are few diseases which continue longer without shortening life; and which, therefore, admit of a more favourable prognosis in respect of a fatal result, or a more unfavourable opinion as regards a perfect recovery. It is chiefly from the consequences of a severe or protracted state of the disease that we are to apprehend any danger; and these are to be ascertained by auscultation and percussion, and our opinions formed accordingly.—a. The circumstances which warrant a *favourable* prognosis as to *recovery* are, a recent attack, and its occurrence from a decided cause; the constitution of

the patient being but little impaired; the absence of deformity and malformation of the chest; a free and easy state of the respiration, and a tolerably healthy condition of the various functions, during the intervals between the attacks. If the occupation of the patient be not injurious to the lungs; or, if so, can be readily relinquished; if the attacks are not extremely severe, nor of very long duration; and more particularly, if auscultation and percussion, as well as the rational symptoms, indicate an uncomplicated state of the disease, we have still greater reason to give a favourable opinion as to its issue.

54. *b.* On the other hand, an *unfavourable* idea must be entertained, especially as respects the perfect recovery of the patient, and his immunity from future attacks, if the fits be very severe; the cough difficult, suffocative, and attended with great expectoration mixed with blood and purulent mucus,—a state of the expectoration generally indicating rupture or dilatation of the small air-vessels, or the existence of tubercles in the lungs. If the occurrence of hæmorrhage from the lungs, of epistaxis, of hæmorrhoids, or of the menses in females, be not followed by a complete solution of the attack;—if the disorder be of long standing, and present remissions merely, or imperfect relief in the intervals, the attacks continuing for several days;—if the means of cure furnish but little or no relief;—if the patient be far advanced in life, and his constitution have suffered much either previously to, or from the malady; and if the body evince signs of cachexia;—if he has neglected his disease, or has been injudiciously treated;—and if the symptoms characterising any of the organic changes which I have stated to proceed from, or to be associated with, asthma (§§ 20—24.), present themselves, particularly dropical effusions in the pleura or pericardium, and the nature and extent of these changes are determined by means of auscultation and percussion, an unfavourable result must be looked for sooner or later; yet may this result be often deferred for a long period by judicious management. The exact degree of proximity of danger will depend entirely upon the nature and extent of the existing organic lesions, and the state of the vital energies of the frame.

55. If the expectoration become purulent, round, and globular; if hectic fever be present, with irregular or intermittent pulse; if palpitations occur, and alternate with leipothymia or syncope; if the urine be in small quantity and high coloured, the hands and ankles being œdematous; if the countenance continue bloated or livid during the imperfect intervals between the attacks; if the patient become restless, with slight wandering or low delirium; a fatal termination is not very far distant, unless under the most favourable circumstances of regimen and medical treatment, when life may be occasionally protracted for some time.

56. V. CAUSES.—1st, *Predisposing causes*. Asthma is not a disease of early life, in its primary or idiopathic form. I have seldom or ever seen it before the 23d year of age. Some authors state that they have met with it in infancy and childhood; but I believe that they have confounded this affection with other diseases of the respiratory organs, and particularly with those to which young children are liable, and which has been termed spasmodic

croup, MILLAR'S asthma, &c. by several modern writers, and its nature very generally misunderstood. The reader will find them treated under other articles. (See LARYNX—*Spasm of*; CROUP—*Spasmodic*; and CATARRH—*Suffocative*.) I believe that affections of the respiratory apparatus in children, which are not connected with inflammation, are generally symptomatic of disease of some other organ.

57. Asthma is evidently sometimes dependent upon hereditary disposition and conformation. It invades all temperaments, but especially the melancholic, the sanguineo-melancholic, the nervous and irritable. The male sex is much more disposed to it than the female, particularly those of the former sex who are of a full habit of body and advanced in life. JOSEPH FRANK surely reckons the proportion of cases in males somewhat too high, when he states that six are affected to one female. So far, however, as my own experience enables me to judge, the proportion is not much less. Persons endowed naturally with great sensibility of the nervous system, or who have acquired this state from indulgence of the passions—from masturbation, venereal excesses, the immoderate use of warm bathing, long continued mental exertions, want of the requisite sleep, frequent excitement of temper, mental depression, and exhausting discharges, are much more disposed than others to be affected by the exciting causes of the disease.

58. The *spasmodic form* of asthma attacks most frequently persons of a spare habit, and who have been weakened or emaciated by the foregoing causes; or who have passed a laborious and anxious existence; whilst the *humoral variety* of the disease is commonly met with in those who are gross, phlegmatic, corpulent, robust, or full of blood, and who have been long exposed to the causes of chronic and general weakness, and have led an indolent, luxurious, or sensual life.

59. In addition to the foregoing causes, sanguineous plethora; malformation and injuries of the lungs, chest, or spine; peculiarities of formation of the air-passages, of the cavities of the heart, and large blood-vessels; constitutional irritability of the air-passages and lungs; narrowness of the glottis, and morbid sensibility and irritability of the nerves and muscles of the larynx; congestions, enlargements, habitual distensions, or organic changes, in the large viscera adjoining the diaphragm, as of the liver, stomach, spleen, and colon; previous disease of the lungs and air-passages, particularly frequent attacks of catarrh, and neglected winter coughs; and adhesions of the pulmonary pleura to the costal or diaphragmatic pleura, may be ranked amongst the predisposing causes of the disease. It should not, however, be overlooked, that the foregoing do not only dispose the system, and particularly the lungs, to the operation of the exciting causes, but are also of themselves capable of producing the disease, when they act intensely, or when their operation is of long duration.

60. Neglected or confirmed *dyspepsia*; erratic or metastatic *gout*; suppressed eruptions, discharges, and habitual perspiration of the feet, are also predisposing and concurrent causes of the disease. In addition to these, I may add, the warmth and closeness of our apartments, luxurious habits, and previous diseases affecting the lungs in a

particular manner—as whooping-cough, measles, small-pox, and typhoid fevers—as having a marked influence in predisposing to asthma.

61. 2d. The *occasional or exciting causes* are, various mental emotions and affections; paroxysms, of anger, vexation, disappointment, anxiety, and all the violent or depressing passions; great fatigue; prolonged watchings; strong exertions of the voice, reading long aloud, or long speaking; terror, or surprise; sudden refrigeration of the surface of the body; or exposure to, and the respiring of a cold or hot, or a too moist or too dry air,—these states of the atmosphere acting differently in different persons and varieties of the disease. Thus, the *third and first* varieties are generally relieved by a dry and pure air, whilst the *second* variety is occasioned or aggravated by it; and a very moist and cold air, or a humid, close, and warm air, whilst it frequently relieves the latter, always augments the former; but it is not infrequently observed, that states of the atmosphere, which cannot be referred to grades either of temperature or humidity, act very differently on different persons labouring under the disease, although the form may be the same. It seems to me extremely probable that this is owing, in a great degree, to the electrical states of the atmosphere, and the electro-motive condition of the frame; as we sometimes see the disease occasioned by close and oppressive states of the air, particularly when these precede a thunder-storm,—thunder and lightning being less influential in its production than the electrical states of the atmosphere which terminate in these phenomena.

62. There are, perhaps, few causes which more frequently produce asthma, than those which act directly on the air-tubes through the medium of the respired air, as various kinds of dust and irritating particles floating in it (see article on ARTS, as *productive of disease*); common coal smoke, the vapour from lime or brick-kilns, metallic fumes of every description, mephitic gases, every kind of acrid vapour, the fumes from chemical manipulations; hydrogen, nitrogen, carburetted hydrogen, carbonic acid gas, and all other gaseous productions floating in the atmosphere; employments which lead those prosecuting them to breathe an air charged with minute particles of vegetable, animal, or mineral productions, as manufactures of cotton and wool, furriers, grinders, needlepointers, &c. Odours of every description occasionally excite the disease, particularly odours acting differently in different persons; those occasioning it in some, alleviating it in others—as the aroma of various flowers and plants, the smell of tobacco, ipecacuanha, &c.

63. The disease may also be produced, or rather a paroxysm may be occasioned in those subject to the disease, by whatever deranges the healthy function of the digestive organs, and particularly if it occasion acid or acrid eructations, which irritate the epiglottis and glottis, or cardialgia, flatulent or inordinate distension of the stomach or colon, or impedes the free descent of the diaphragm (*Ast. Stomachicum*, BAGLIVI; *Ast. Flatulentum*, FLOYER, SCHROEDER, BALDINGER), and by irritation and spasm of the glottis and trachea, (WILLIS, LILIENTAUD, DESGRANGES, &c.). It is also sometimes occasioned in the female by hys-

terical affections (*Ast. Hystericum*, HORSTIUS, BAGLIVI, SAUVAGES, &c.); by misplaced, suppressed, or metastatic gout (*Ast. Arthriticum*, MUSGRAVE, HOFMANN, STOLL, &c.); by the syphilitic poison (*Ast. Venereum*, JÜNCKER); by the slow introduction of lead into the system (WILLIAMS; *Ast. Metallicum* of EITMULLER and ILSMANN); by great obesity (FLOYER); the suppression of accustomed discharges and evacuations, and from vascular plethora proceeding from this cause (*Ast. plethoricum*, DOVER, CULLEN, SAUVAGES; *Ast. Sanguineum*, HOFFMANN); by the repulsion of eruptions, the retrocession of exanthematous diseases, and the drying up of issues and eruptive discharges (*Ast. Exanthematicum*, CULLEN, et VAR. AUCT.). It may also proceed from a cachectic habit of body (*Ast. Cachecticum*, HOFFMANN, SAUVAGES, &c.); from excessive impregnation of the system with mercury (SCHENCK, BONET); and from chronic catarrh and bronchitis (LAENNEC, BOISSEAU, &c.).

64. 3d, *Symptomatic Asthma*.—But little is required to be added under this head, further than to specify in a general way some of the organic lesions that sometimes excite phenomena which either closely resemble, or are the same as, those which accompany the idiopathic disease. Amongst those, the disturbance of the pulmonary circulation, and the nervous and muscular irritation, occasioned by organic lesions of the heart and large vessels; by aneurismal tumours; by tumours affecting the diaphragmatic and pulmonary nerves (BÉCLARD, ANDRAL, and PARRY); enlargement of the cavities of the heart, and obstacles to the circulation through the openings into the ventricles or arterial trunks; by ossific deposits in these situations, or in the coats of these vessels, or in the external surface of the heart, or pressing on the pulmonic plexus of nerves (FERRUS); by polypi in the cavities of the heart and large vessels (DIEMERBRÖCK, FLOYER, ROSTAN); by adhesions of the pleura, and organic changes of the parietes of the chest, diaphragm, or spine; by curvatures of the spinal column, and lateral contraction of the chest, &c.; by hernia of the diaphragm (HECKER, BONET); by tumours and effusions within the chest and pericardium; by organic changes in the vicinity of the larynx and trachea; by enlargement of the lymphatic glands within the chest and the glands of the bronchi; by tumours developed in the mediastinum (SCHÄFFER); by foreign substances which have escaped into the trachea and bronchi; by organic changes of the lungs, themselves, especially miliary tubercles, or similar productions in advanced stages of growth and change; by œdema of the lungs, or sero-sanguineous infiltration of their substance; and frequently by emphysema of the organ, and pituitous collections in the bronchi, the emphysema being a very common consequence and complication of the severer forms of the disease (BAILLIE, LAENNEC, &c.). Besides being sometimes induced by one or more of the above lesions, it may also be symptomatic of congestions and organic lesions of the liver and spleen; but, although those, and various other organic lesions enumerated under DYSPŒA, produce spasmodic and convulsive states of impeded respiration in some rare instances, yet they are more commonly productive of continued or remittent dyspŒa. Asthma is, moreover, some-

times symptomatic of lesions affecting the *medulla oblongata* and spinal chord, of *hypochondriasis*, and of diseases of the colon and rectum.

65. VI. COMPLICATIONS OF ASTHMA.—From the foregoing statement, it will be readily admitted that asthma very frequently presents itself in practice in complicated forms. Indeed, when the disease occurs in consequence of any of the states of the system described in §§ 60—64., or of any of the previously existing diseases and organic lesions of which I have stated it occasionally to be consecutive and symptomatic, it should be viewed as complicated with such lesion, and our attention directed to the whole of the morbid association, both pathologically and therapeutically. Our inquiries should likewise be extended even to the functions of distant organs, as it will occasionally have an intimate relation even with them, particularly to the functions of the digestive, assimilative, and generative organs. Amongst the most common complications of the disease, I may mention the various forms of *catarrh*, *dyspepsia*, *hypochondriasis*, *hysteria*, *emphysema* and *adema of the lungs*, *hæmoptysis*, *chronic bronchitis*, and *disease of the heart*, as especially requiring our attention during the treatment. (See the articles LUNGS and BRONCHITIS.)

66. The paroxysm of the *third* variety of disease is often occasioned by a common *catarrh*; and owing to this circumstance, as well as the presence of many of the symptoms of this affection, it has often been denominated *catarrhal asthma*. It is sometimes also complicated with active congestion of the lungs, particularly of their mucous surface. Dr. PARRY conceived that this state of the respiratory organs constitutes the disease; and instances the case of a person, who died in about twenty minutes with all the symptoms of spasmodic asthma, and in whom the only lesion was complete suffusion, of a dappled rose colour, amounting in parts almost to a blackness of the mucous membrane of the trachea and bronchi. *Dyspepsia* not only accompanies asthma, but very generally precedes an attack. The complication with *bronchitis* and *hæmoptysis* is chiefly observed in the third variety; whilst the association with *hysteria* and *hypochondriasis* is most commonly met with in the nervous and spasmodic forms of the disease.

67. *Organic diseases of the heart*, and large vessels are very frequently complicated with asthma. The former seems to be most commonly a consequence of the latter; but, in some cases, an opposite order of causation obtains. In all such states of disease, either too little, or too much blood enters the lungs, and the healthy relation between respiration and the pulmonic circulation is changed; if either too much, or too little blood passes, it is imperfectly purified, and the wants of the system occasion a sense of anxiety and anhelation. But I believe that the phenomena of associated disease of the heart, and of the pulmonary functions, may be more correctly explained by referring them to the state of the nerves supplying the organs. These nerves are so intimately related, anatomically and physiologically, that disease originating in, or affecting, any one part of them, will frequently influence the functions of the whole, or of such of them as are most intimately connected with the originally

diseased part. When, therefore, we find a portion of the particular order of nerves, which supplies the respiratory and circulating organs, remarkably affected—whether such portion influence the state of the bronchi, or the circulation through the lungs, or the actions of the heart—can it be a matter of surprise that an analogous disorder should extend to parts so intimately related anatomically and functionally as are the air-passages, the pulmonic circulation, and the heart and large vessels?

68. Upon taking a review of the causes of this malady, we shall perceive that it may be occasioned, like several other chronic diseases of the respiratory organs,—1st, By whatever lowers the vital energies of the frame, particularly as they are manifested in the lungs, and increases the susceptibility of the organ to the impression of external agents, or to internal morbid associations (§ 57.);—2d, By mental or moral states deranging the nervous influence actuating the respiratory and circulating organs (§ 61.);—3d, By agents which disturb the equilibrium existing between the cutaneous and respiratory functions (§ 61.);—4th, By causes acting, during respiration, directly on the seat of disease, either by depressing the vital and nervous influence of the organ, or by irritating its mucous surface, and thereby exciting its fibrous structure to undue contraction (§ 62.);—5th, By causes acting during respiration, especially aerial vicissitudes and states which mollify or impede the respiratory functions, and favour congestion of the pulmonary mucous surface, or of the substance of the lungs;—6th, By whatever impedes the action of the respiratory muscles, or embarrasses the motions of the parietes of the chest (§ 63.);—7th, By lesions of the circulating organs deranging the circulatory function of the lungs or heart (§ 64.);—8th, By the extension of irritation from adjoining viscera or parts (§ 64.);—9th, By the destruction of the equilibrium between absorption and excretion (§ 58.);—10th, By the transference of morbid action from other parts of the frame (§ 63.);—11th, By affections of the respiratory nerves and plexuses, either at their origins, or in any part of their distributions (§§ 57. 64. 67.). Hence the propriety of dividing asthma not only into the *nervous, spasmodic, and humid varieties*, but also into *two divisions*, as respects its relations to its causes, and to other diseases; viz. into *IDIOPATHIC* and *SYMPTOMATIC*.

69. VII. PROXIMATE CAUSE.—The majority of writers on this disease, from WILLIS down to the times of HOFFMANN and CULLEN, have referred it to spasm of the bronchial tubes; and the same opinion has been espoused by many contemporary authors, particularly LAENNIC, WILLIAMS, &c. ROSTAN and several French pathologists consider the disease as altogether symptomatic of organic changes seated chiefly in the heart and large vessels; but although this may be conceded to be the case occasionally, I conceive that they substitute the effect for the cause; lesions of these organs necessarily supervening in the manner already explained (§ 67.), after repeated attacks. The doctrine, moreover, has been completely overturned by the post mortem examination of cases of the disease by CONVESART, FERRUS, GEORGET, LAENNIC, ANDRAL, DILLENS, and BRICHTEAU, in which no such

changes were found. BREE, PARRY, and BROUSSAIS ascribe asthma to inflammatory congestion and irritation of the mucous membrane lining the air-passages; and this doctrine is at present adopted by many British and continental pathologists. I do not mean to dispute the existence, to a certain extent, of irritative congestion of the respiratory mucous surface, particularly in the *third variety* into which I have divided the disease; but still I believe that it is a part only of the changes from the healthy state, which constitute this malady. M. GEORGET contends that it proceeds from irritation about the base of the brain, and particularly at the upper part of the medulla oblongata, and origin of the respiratory nerves, occasioning convulsive prooxysms of the inspiratory muscles. MM. ROCHE and SANSON (*Éléments de Pathologie*, &c. t. ii. p. 642.) ascribe it to irritation of the nerves supplying the respiratory surfaces, occasioning convulsive actions of the respiratory muscles; ZALLONY to suppressed influence of the pulmonary nerves, and imperfect change of the blood in the lungs; DUPUYTREN to an affection of the par vagum; and HORN, HENKE, and many others, entirely to spasm of the bronchi. That the disease, in a great measure, depends upon the morbid state of the nerves supplying the lungs and respiratory muscles, is evinced by the case which occurred to M. FERRUS, who found, on the dissection of a female who had been subject to spasmodic asthma, a considerable ossific deposit in the centre of the pulmonic plexus, and compressing part of its nerves. There can be no doubt that irritation of the nerves, or impeded or interrupted nervous influence will produce spasm of those muscular parts, which they supply, and interruption of those functions which are dependent on their healthy influence.

70. The proximate cause assigned to the disease by CULLEN, PARR, and other modern authors, differs but little from that contained in the writings of WILLIS, BAGLIVI, HOFFMANN, BORRHAAVE, SAUVAGES, and others of their predecessors, excepting that it is stated by them with greater precision. It seems to me so correct, in the majority of cases, as not to admit of dispute. Doubtless the researches of contemporary pathologists have tended to show that many cases closely resembling this disease, and which would have been imputed to the same pathological states as they were imputed by our predecessors, depend on other conditions of the respiratory organs, and those differing widely in their nature from each other; thus abridging the number of purely asthmatic cases, and consigning to different organic lesions many that present nearly similar functional derangements to those which are strictly asthmatic.

71. I therefore conclude, with many of my predecessors, some of them unmeintedly overlooked at the present day, that asthma depends on a preternatural or spasmodic constriction of the air-passages, accompanied in many cases, especially in the humoral or catarrhal variety, and particularly when it assumes what M. LAENNIC has called the dry catarrhal form, with turgescence of the vessels of the lungs, particularly those supplying their mucous surface, and an increased secretion of mucus; and I would add, that, in this form of the disease, the spasmodic constriction of the air-tubes, the turgescence of their mu-

ous lining, and the accumulation of mucus in them, present an obstacle, not only to inspiration, but also to expiration; the lungs being thereby often kept in a state of inordinate dilatation, and the respiratory muscles excited to convulsive efforts, occasioning, in some cases, dilatation of the air-cells, or their rupture, and consequent emphysema of the organ, with effusions into the air-tubes, and other consequences described in the article on *Organic Diseases of the LUNGS*.

72. VIII. TREATMENT.—The treatment of asthma is generally directed to the fulfilment of two intentions; viz. to shorten or alleviate the fit; and to prevent its return, and thus remove the disease. The means of cure may therefore be divided, 1st, into those which are to be resorted to during the paroxysm, with the view of attaining the first intention; and, 2d, Such as may be employed during the interval, for the accomplishment of the second. I shall notice successively the measures which may be resorted to for the fulfilment of these ends, with as strict a reference to the forms and complications of the disease as my limits will permit.

73. 1st. *Treatment of the paroxysm.*—In treating the fit of asthma, the practitioner will take cognizance of certain particulars, which should materially influence the choice, the combination, and the extent of the means which are to be put in operation. The duration of the paroxysm; the age, temperament, and habit of body of the patient; the period he has been subject to the disease, the frequency of the attacks, and the particular form they assume; the state of health in the interval; and the presence or absence of concomitant, functional, or organic lesions of the lungs, heart, and digestive organs, are all of the utmost importance to be known; and, without tolerably accurate ideas respecting them be entertained, the disease cannot be judiciously treated. As individual cases vary greatly as to each of these circumstances, it would be impossible to describe in connection all the measures which may be employed in a paroxysm of asthma, so as to be appropriate to each of its numerous states and complications. Such descriptions, although they would be sometimes perfectly suited to a case, would as often be inappropriate, or even altogether inapplicable. I shall, therefore, detail separately the means of cure which have been found most beneficial, and point out the states and circumstances of the disease to which each of them seems best suited, at the same time arranging them in such a manner as to fulfil intentions of cure, based on the pathology of the disease.

74. *A. To remove congestion or repletion, when present.*—There are various symptoms which frequently present themselves during the asthmatic paroxysm, which would suggest the propriety of blood-letting. But it is often either of little service or positively prejudicial, especially in the first two varieties of the disease. In the third variety, however; and in the young, robust, middle-aged, and plethoric subj ct; or when the paroxysms are very severe, and are attended with signs of much congestion of the lungs and brain, as lividity and fulness of the countenance, stupor, extreme dyspnoea, &c.; blood-letting is indispensable, and should be performed either from the feet, or by cupping between the shoulders.

Yet, even in these cases, bleeding will seldom do more than relieve the more urgent symptoms: it will seldom or ever put a stop to the paroxysm, and it should be practised always with much caution.

75. *B. To moderate or relieve spasm by anti-spasmodics, anodynes, and narcotics, &c.*—These medicines may be viewed in connection, as a combination of them are more suited to the asthmatic fit, than the exhibition of them singly. They are beneficial chiefly in the first and second varieties of the disease, and in the third, when attended with severe convulsive and spasmodic fits of cough. When the disease occurs in hysterical females, or is associated with organic change of the heart or large vessels, these medicines are generally of much service. In the humoral form of the disease, and particularly when it commences, or is complicated with catarrh, they are less serviceable, although sometimes beneficial when judiciously employed. The particular remedies belonging to the above classes, which have received the approbation of the best authors, are *camphor, asafoetida, valerian, castor, musk, ammonia, athers, coffee, opium, stramonium, tobacco, belladonna, hyoscyamus, conium, hydrocyanic acid, colchicum, digitalis, luctuca sativa, &c. &c.*, in various forms, and modes of combination.

76. *a. Camphor* is one of the most generally beneficial of any of this class of remedies, and is, when judiciously exhibited, applicable to nearly all the forms and complications of the disease. In the nervous and spastic varieties it is most serviceable when given in large doses (from three to ten grains), and combined with musk, castor, asafoetida, and the preparations of ather, opium, or hyoscyamus (see F. 25. 186. 423. 493.), and the following:—

No. 34. R. Camphoræ rasæ, gr. iij.—vi.; Ammon. Sesqui-Carbon. gr. iij.; Pulv. Ipecacuanhæ gr. j.; Extr. Hyoscyami gr. iij.—v.; Mucilag. Aca. iæ q. s. M. Fiat Pilulæ iij. statim sumendæ cum Haustu sequente, et horas post binas repetendæ, si sit opus.

No. 35. R. Magnes. Carb. ℥j.; Aq. Anethi ʒx; Spirit. Æther. Sulph. Comp. ʒj.; Tinct. Castorei ʒj.; Olei Anisi ℥iv. M. Fiat Haustus.

77. In the pituitous or catarrhal form of the disease, or in cases where blood-letting may be practised, and where we suspect active congestion of the mucous surface of the air-tubes, camphor is best exhibited in moderate doses, and combined with nitrate of potash, ipecacuanha, kermes mineral, James's powder, and other antimonials (see F. 494—496.).

No. 36. R. Pulv. Jacobi Veri gr. iij.—vj; Camphoræ rasæ gr. ij.—iv.; Pulv. Ipecacuanhæ gr. j.; Ext. Hyoscyami gr. iij.—vj.; Syrupi Papaveris q. s. M. Fiat Pilulæ iv., quarum capit binas statim, et alteras post horam, vel omnes horâ decubitis.

No. 37. R. Camphoræ rasæ gr. j.—iij.; Antimonii Pot.-Tart. gr. ss; Potassæ Nitratiss gr. v.—viij; Moschi gr. ij; Extr. Opi gr. ij.—iv. (vel Ext. Lactucæ gr. iij.—v.); Olei Anisi q. s. ut fiat Pilulæ iv., quarum capit binas statim, et alteras post horam, vel sumat omnes horâ somni.

78. *b. Asafoetida, castor, musk, valerian, myrrh, ammonia, the balsams, the trisnitrate of bismuth, the preparations of zinc, and the athers,* may be severally exhibited in the same states of the disease. They are more beneficial in the nervous and spasmodic varieties, when unassociated with inflammatory irritation, particularly in chronic cases, in the debilitated or aged; and in the third variety, occurring in persons of a relaxed and leucophlegmatic habit of body,—a conclusion which is conformable to the experience

of MILLAR, RENARD, SCHLEGEL, WOLFF, DOVER, REIDLIN, BANG, SCHMIOTMANN, WICHMANN, LENTIN, KRETSCHMAR, LOEBEL, HUFELAND, and BERNHARD, and which will be justified by future observation, notwithstanding the doubts of their efficacy which have been entertained by some writers, who consider asthma as merely a form of inflammation of the mucous surface of the air-passages. They may be conjoined with one another, or with narcotics; and may be advantageously administered, particularly assafoetida and valerian, in the form of clyster.

79. Although these antispasmodics are indicated chiefly in the forms of the disease above alluded to, they need not be restricted to them entirely. When combined judiciously, as either with *antimonials*, or with *colchicum*, *opium*, *digitalis*, *nitrate of potash*, *camphor*, *ipecacuanha*, *hyoscyamus*, *conium*, &c., and given in suitable doses, according to the peculiarities of the case, they will be productive of much benefit, in other states of asthma, both in the paroxysm and in the intervals. The external application of them, especially of camphor, assafoetida, galbanum, ammoniacum, &c., in the form of plaster, and particularly in conjunction with opium or with belladonna, will sometimes prove of much service. (See F. 112, 113.)

No. 38. R Extr. Opii, Camphoræ, āā ʒ ij.; Emplast. Galbani Comp. ʒijss.—ʒ ss. Fiat Emplastrum secundum artem, scuto pectori admovendum.

80. c. Besides the beneficial effects produced by it as an emetic, *ipecacuanha* is, when used with this or other intentions, one of the best medicines that can be resorted to in asthma, as being suited to all the states of the disease, particularly when judiciously combined with other substances. It may be associated with nitre, or colchicum, or digitalis, or with antimony, camphor, and narcotics, in the more febrile and catarrhal states of the disease (see F. 39, 394.); and with assafoetida, or with castor, benzoin, the spirits or oil of aniseed, valerian, opium, &c., in the more nervous or spasmodic varieties. (See F. 857, 900.)

81. d. The distilled *laurel water* or the *hydrocyanic acid*, particularly the latter, is often productive of much benefit in the paroxysm. I have found it of great advantage when given in from two to four drops at the accession of the paroxysm, and in small doses in the intervals, particularly when the disease is attended with much irritability of the stomach and flatulence. It may be conjoined with camphor, ipecacuanha, æther, capsicum, &c., or, indeed, with any of the medicines already mentioned. (See F. 344.)

82. e. Of the narcotics, *opium*, *hyoscyamus*, *conium*, *stramonium*, and *belladonna*, are the most commonly used. The best preparation of opium in this malady is the compound tincture (see F. 729.); and it is most advantageously combined with camphor, aniseed, any of the æthers, or the wine of antimony or of ipecacuanha, according to the circumstances of the case. I have tried the *acetate of morphine* in this disease, as a substitute for opium, but with no benefit, unless when combined with stimulating antispasmodics; in which form, either the *sulphate* or the *hydrochlorate of morphine* may occasionally be employed. *Hyoscyamus* and *conium* are often uncertain remedies; but when their preparations are genuine, they are very useful adjuvants, par-

ticularly the former; and, if judiciously prescribed, applicable to every state of the disease. The combination of *hyoscyamus* with the *infusion of valerian* has been much praised by LOEBEL in the spasmodic form of asthma.

83. f. *Belladonna* has been found serviceable when combined with stimulating antispasmodics, particularly camphor, valerian, or assafoetida; but it requires caution. In conjunction with ammonia, galbanum, or assafoetida, &c. in the form of plaster (§ 79.), it will sometimes be productive of much benefit. The *lactuca sativa* will be also employed with advantage, under similar circumstances to those in which the above narcotics are beneficial. SCHLESINGER and WOLFF advise two or three grains of its extract to be given, either alone, or with half a grain of digitalis, every two hours.

84. It may be observed generally, that narcotics can seldom be productive of any effect under a certain space of time, which will vary with the susceptibility of the patient. In many cases they will have no marked influence under two, or even three or four hours, at which time the severity of the fit will often subside without medicine. When given by the stomach, therefore, this circumstance should be kept in recollection; and should induce the practitioner to ascertain the period of accession or aggravation of the paroxysm, and to regulate the periods at which these, as well as other remedies, are to be exhibited, in such a manner as that their anticipated action may be contemporaneous with the commencement of the fit. As the attack consists generally of a series of paroxysms or exacerbations, medicines should be continued in suitable doses, and with reference to this circumstance, until it terminates. It will be found always advantageous to prescribe a full dose of the narcotic at once, in order that its effects may be secured as soon as possible. When any one or more of the stimulating antispasmodics, particularly camphor, ammonia, or musk, are combined with narcotics, a very large dose of the latter may be exhibited. Narcotics are most quick in their operation, when their vapour or smoke is inhaled into the lungs. Their effects are longest delayed when they are applied to the external surface; unless the cuticle has been previously removed, as in the "*en lermic*" method of medication. The inhalation of the vapour of certain of this class of remedies, either alone or in conjunction with some volatile vapours, is one of the most certain and quick modes of obtaining relief in the asthmatic paroxysm.

85. g. *Stramonium* is one of the best remedies that can be prescribed in the spasmodic form of asthma. It is principally used by smoking it as tobacco. During this process, the patient may either draw a portion of the smoke into the lungs, or swallow some of it, or the saliva which has become impregnated with it. *Stramonium* is very advantageously smoked along with aniseed, or with a small portion of tobacco. It may also be employed internally during the asthmatic paroxysm, as follows:—

No. 39. R Pulv. Fol. Stramonii gr. j.—ijj.; Sodæ Carbon. exsic. gr. vj.; Olei Anisi q. s. ut fiant Pilulæ ij. statim sumendæ.

No. 40. R Succo Inspissati Stramonii gr. ss.—gr. j.; Potassæ Carb. gr. vij.; Olei Cajuputi q. s. M. Fiant Pilulæ ij. pro dose sumendæ.

86. The smoking of *tobacco* is one of the most generally employed and efficacious remedies we possess for this disease; but it is productive of marked benefit only when it excites a free expectoration. The tobacco may be used in this manner along with *aniseed*, or with *stramonium*, or *both*. The internal use of preparations of tobacco, as of its infusion, tincture, wine, &c., so, as to excite nausea, has also been recommended in the paroxysms of asthma by ETTMULLER, MICHAELIS, and several German writers.

87. *h. Lobelia inflata*, or Indian tobacco, has been much employed in America in asthmatic cases. It is nearly allied in its operation to stramonium and tobacco; and often succeeds in checking the paroxysm, when given at its invasion, or very shortly before. It sometimes, however, fails of having any good effect, unless it be taken to the extent of producing nausea and vomiting. From six to fifteen or twenty grains of its powder may be prescribed for a dose, or from half a drachm to two drachms of a saturated tincture of its leaves (℞ j. to O ss.)

88. *i. Inhalation of emollient and medicated vapours, gases, &c.*—Next and, perhaps, equal to smoking, is the inhalation of simply emollient or of medicated vapours into the lungs. This method of treatment was recommended by CÆLIUS AURELIANUS, ALBERTI, MUDGE, BEDDOES, THILENIUS, ZALLONY, HUFELAND, CRICHTON, FORBES, GANNAL, SCUDAMORE, and MURRAY. It is chiefly indicated during the paroxysm, or shortly before its accession. The vapours arising from pouring boiling water upon camphor, any one of the narcotic extracts or tinctures, or the balsams, are of great advantage when properly managed. Thus the vapour from a pint of boiling water poured upon half an ounce of balsam of tolu; or that from a solution of camphor, balsam of tolu, and extract of lettuce, or of conium, in sulphuric æther; or the fumes proceeding from camphor, hyoscyamus, and aromatic vinegar, mixed together, and quickened by the addition of some boiling water, may be employed. A solution of balsam of tolu in sulphuric æther, the vapour of boiling tar diffused in the air of the patient's chamber, chlorine gas much diluted with common air, and various other medicated vapours, may be tried; but these act chiefly by removing the viscid phlegm which collects in the bronchi, and by exciting the extreme exhaling vessels. I have prescribed the vapour of the *sulphuret of iodine* in two cases: in one of spasmodic asthma, with no benefit; and in one of humoral asthma, with only temporary advantage. Sir C. SCUDAMORE recommends this formula for the inhalation of iodine—R Iodini gr. viij.; Potassii Iodidi gr. v.; Alcoholis ℞ ss.; Aquæ Desil. ℞ vss. M. Fiat Mistura. To this he adds tincture of conium. But his directions as to quantity and mode of inhalation are, notwithstanding several attempts to unravel them, perfectly beyond my powers. I believe, however, that portions only of the above mixture should be employed for each inhalation. But the observing practitioner will generally be able to apportion the quantity, as well as to direct the particular materials, for inhalation, according to the peculiarities of the case; bearing in recollection that the combination of narcotic and anodyne vapours with volatile fumes and gases will generally be of more service

in asthma than the use of individual substances belonging to one only of these classes of medicines; and that the more irritating substances of this description, such as iodine, chlorine, and tar vapour, should be ventured upon only in a very weak or dilute state.

89. *C. To remove viscid phlegm, and to prevent its formation.*—*a. By expectorants, &c.* Squills are amongst the most frequently prescribed medicines for this purpose, in asthmatic attacks; but they are certainly not applicable to all its states, although they, as well as *ammoniacum*, *inula helenium*, and *senega*, are very generally recommended by some of the best medical writers. The good effects of these medicines in certain manifestations of asthma cannot be doubted; but I have seen them productive of much mischief in several cases in which they had been employed. It should be kept in recollection, that they are amongst the most active excitants of the respiratory mucous surfaces we possess, and are extremely apt to change active congestion of the bronchial lining into inflammatory action, especially in young, plethoric, or robust subjects; and, by their effect upon the expectoration—particularly by increasing it, rendering it thinner, less viscid, and more readily expectorated—to occasion a deceptive appearance of benefit, even when they are increasing morbid action, with all its ill effects. In relaxed and leucophlegmatic habits, however, or when the expectoration is viscid, and excreted with difficulty; the skin cool, soft, and moist; the pulse soft, slow, or weak, and the urine scanty; these medicines may be given with great benefit (see F. 66, 67, 74. 353.): but when the pulse is either hard, quick, or full; or the expectoration at all puriform; they cannot be exhibited without risk. They will often, doubtless, even in cases of active congestion of the respiratory mucous surfaces, afford real benefit, by exciting the capillaries to secretion, and thereby unloading them; but they may as readily kindle up inflammatory action. When combined, however, with antimonials, refrigerants, diuretics, or anodynes, the risk of mischief from them in doubtful cases is much reduced. ALBERTI, FLOYER, WAGNER, SCHULZE, LENTIN, and BREE advise squills in the pituitous form of the disease, and found them most serviceable when they produced nausea or vomiting,—the benefit being, perhaps, more to be attributed to this operation, than to the medicine which occasioned it. Under the circumstances in which I have admitted the use of ammoniacum, squills, inula helenium, benzoin, and senega,—namely, in the chronic pituitous asthma,—the Formulae in the Appendix above referred to, or the subjoined, may be prescribed:—

No. 41. R Scillæ exsic. gr. xij.; Myrrhæ ℞ ij.; Extr. Hyoscyami ℞ ss.; Olei Anisi q. s. M. Fiat Pilulæ xvij., e quibus sumantur binæ quartis vel sextis horis.

90. *b. Emetics* are amongst the most promptly beneficial remedies that can be resorted to during the paroxysm, with the intention of removing both phlegm and spasm; and they have been justly recognised as such by CÆLIUS AURELIANUS, HORISTUS, MAYERNE, FLOYER, AKENSIDE, BANG, KERBS, HUFELAND, WEDEL, STOLL, BREE, LOEFFLER, and SCHMIDTMANN. *Ipecacuanha* is, upon the whole, the best medicine that can be employed to produce this effect. The philosophical AKENSIDE recommended a scruple of it to be given at the commencement of the paroxysm, and five grains every morning during the intervals, for some time, so as to occasion nausea. When the paroxysm is excited by an overloaded or deranged state of the stomach, emetics are particularly indicated. It is in such cases that SCHMIDTMANN, one of the most practical and experienced of modern writers, recommends them; whilst STOLL and LOEFFLER advise them principally in the humoral form of the disease. In the asthma to which several classes of artisans, particularly pearl-turners, &c. (See ARTS, and the *Causes of Disease*), are liable, emetics have been found the most successful remedy in the paroxysm. But, besides this operation, *ipecauanha* has an especially beneficial effect in asthma, as I have already particularly noticed. Next to it, and even superior to it in the very humid states of the disease, are the preparations of zinc, particularly the sulphate, in suitable doses and forms of combination (see F. 582—587.).

91. *c. Nearly allied to emetics are nauseants and diaphoretics.* These are sometimes of service, either at the commencement, or shortly before the fit. The substances that may be employed to produce this effect are *ipecauanha*, and the different preparations of antimony, particularly the potassio-tartrate and kermes mineral. These latter are praised by BANG, VICAT, and HUFELAND. *Ipecauanha*, in from one to five grains, or the antimonials in full doses, may be combined with nitre, camphor, opium, or hyoscyamus, according to the circumstances of the case (see F. 393. 854.).

92. *d. Refrigerants.* Of this class of medicines the most useful is the *nitrate of potash*, in conjunction with camphor; *ipecauanha*, and *hyoscyamus* (F. 279. 431. 436.), particularly in the humoral variety of the disease; in the state described as requiring blood-letting; or when the attack has been induced by, or is complicated with, catarrh. Either of the following draughts may be taken at the commencement of the paroxysm, and repeated in two hours, if necessary:—

No. 47. R. Potassæ Nitratæ gr. x.—xx.; Spirit. Æther. Nit. ʒj.; Vinî Ipecauanhæ ʒj.; Tinct. Hyoscyami ʒj.; Mist. Camphoræ ʒj.; Syrupi Tolutani ʒj. M. Fiat Haustus statim capiendus.

No. 48. R. Potassæ Nitratæ gr. x.—xvj.; Vinî Ipecauanhæ, Tinct. Hyoscyami, ʒā ʒj.; Liquor. Ammon. Acetat. ʒij.; Mist. Camphoræ ʒj.; Syr. Tolutan. ʒj. M. Fiat Haustus statim capiendus.

93. Besides the internal use of refrigerants, LOEFFLER recommends cold epithems to be placed on the chest, in the spasmodic form of the disease; and several Continental writers advise clysters of

cold water to be administered when asthma seems to be connected with hysteria. In such cases, clysters of assafoetida or of infusion of valerian are preferable. Refrigerants act both by diminishing inordinate secretion, and by allaying spasm; and, when the disease is connected with active congestion, or excitement, are, with depletion, the safest measures that can be employed to remove, or to prevent the formation of phlegm.

94. *D. To transfer irritation to other parts,* or to recall the disease to its original seat, when it has arisen from the metastasis of gout, rheumatism, or the suppression of discharges, is often an important indication. The usual means of *revulsion and derivation*, or counter-irritation, particularly those which produce this effect with the greatest celerity, as *sinapisms, stimulating pediluvia, and the vapour bath*, are the chief revulsants that are admissible under such circumstances and at this period. They may be accompanied with diaphoretics, aperients, diuretics, or even emmenagogues, in particular cases. They have also occasionally been found successful in preventing the accession of the fit; particularly if employed when the premonitory signs first appear; and if internal derivatives, especially a purgative combined with antispasmodics and carminatives, have preceded them, and if they have been followed by gentle diaphoretics. *Warm turpentine epithems*, placed on the chest, are often remarkably beneficial. The *turpentine liniments* (F. 300. 311.) may also be employed in a similar manner.

95. *E. To remove flatulence, by means of gentle aperients combined with carminatives,* is often necessary during the course of the paroxysm. I have observed much benefit derived from the exhibition of a purgative, combined with antispasmodics and carminatives, shortly before the expected accession of the attack, particularly when the premonitory signs begin to appear, and the digestive organs evince disorder—such disorder often acting as the efficient cause of the seizure. (See F. 28. 181. 266. 379.) The combination of diuretics, also, with the medicines prescribed during the paroxysms, or of carminatives, in order to relieve the distressing flatulence with which they are very generally accompanied or preceded, will be often found of service.

96. *F. Besides the means noticed above, there are several which have been recommended in the fit—some of them most deservedly, others in a very indiscriminating, and hence not a very beneficial manner.* Of the former of these, *warm coffee* is the most important. This dietetic remedy was used by FLOYER in this disease, and more recently by THILENIUS, PERCIVAL, and BREE. It generally affords much relief when made sufficiently strong; and it seems to resemble the stimulating antispasmodics, particularly camphor, in its action. I have also observed the paroxysm checked by strong *green tea*.

97. My limits oblige me merely to enumerate the other medicines which may be resorted to in the paroxysms of asthma. The chief of these are, *dry cupping* between the shoulders, a weak solution of *phosphorus* in ether, the trisnitrate of *bismuth* and oxide of *zinc, nux vomica*, &c., by several Continental writers; *galvanism*, as recommended by Dr. W. PHILIP; *electricity*, by M. SIGAUD LAFOND; the *chenopodium ambrosioides*, by HUFELAND; the infusion or spirits of juniper, by BEKKER;

guaiacum, by AASKOW, particularly when the attack occurs in the gouty or rheumatic diathesis; cajuput oil, in the spasmodic form of the disease, by WICKMANN; the veratrum album, by MÜLLER; the hydrochlorate of ammonia, by MANTUS; and the external application of garlic, by PORTAL.

98. 2d. *Treatment during the interval.*—Our chief object during the interval is to prevent the accession of the attack, by avoiding the remote causes, and removing the morbid state of the digestive and respiratory organs which dispose to it, and whatever disorder of function or of structure with which the disease may have become associated. We should, therefore, endeavour to form a correct opinion respecting the state of the bronchial mucous surface, the morbid associations of the affection, and the consecutive lesions which may have already supervened to it. The state of the digestive functions, of the alvine secretions and excretions, should receive the utmost attention; and the means which may be most appropriately used for their promotion, in particular cases, ought to be assiduously employed.

99. A. *Evacuations, &c.*—Under this head I will briefly consider blood-letting, emetics, purgatives, blisters, issues, and diaphoretics.—*a. Bleeding* is seldom of service in the uncomplicated state of the disease. But when it is accompanied with vascular plethora, or pulmonary congestion; or when the attack seems to have been produced by the suppression of an accu-tomed discharge, whether sanguineous or of any other description; a moderate blood-letting or cupping between the shoulders, will be of advantage.

100. *b. Emetics* during the intervals are only required when the disease is characterised by congestion of the mucous surface of the lungs, obstruction of the bronchi by a viscid secretion, or torpid and loaded state of the liver and biliary apparatus. When prescribed shortly before the expected fit, they often succeed in preventing its accession.

101. *c. Purgatives* are often necessary; but they may also be detrimental. Those substances which irritate the digestive mucous surface, without producing a full feculent evacuation, are always prejudicial. Purgatives also are hurtful when they are employed so frequently as to lower the vital energies, and carry off a portion of the chyle which should be absorbed into the circulation. On the other hand, stomachic aperients and purgatives exhibited in combination with tonics and antispasmodics, and to the extent merely of promoting the digestive, assimilating, secreting, and excreting functions, are particularly beneficial. Either of Formulæ 266. 450. to 456. 462., contained in the Appendix, or the following, may be prescribed:—

No. 49. R Aloë Socot. gr iv.; tere benè cum Gum. Mastich. gr. ij. et addè Extr. Gentianæ Comp. et Mass. Pilul. Galbani Comp. aa gr. ij.; Olei Anisi q. s. Fiant Pilulæ iij. hora somni quotidie sumenda.

102. *d. Diaphoretics* in small doses, in conjunction with anodynes, deobstruents, or antispasmodics, are of service merely in as far as they may preserve a regular state of an important function, and prevent the determinations to internal organs which frequently follow any interruption to it. But profuse perspirations and warm bathing are more generally prejudicial than otherwise. Indeed, whatever relaxes the cutaneous surfaces beyond a certain degree has an injurious effect upon affections of the lungs which

are not acutely inflammatory, and particularly in the pituitous chronic asthma. When the paroxysm is associated with the dry catarrh, diaphoretics may be carried further with advantage; and when combined with expectorants and antispasmodics (§ 91.), they are more generally applicable.

103. *B. Expectorants, alterants, attenuants, and deobstruents*, or substances supposed to have some one or more of these effects, have been very generally recommended in asthma. Several of these have little or no effect, and others may even be injurious.—*a. The expectorants* most frequently employed are those already noticed; but I believe that they are seldom productive of much advantage, given in the interval. When the disease is complicated, as it not infrequently is, with dry catarrh, or irritation of the bronchial mucous surface, those substances which have the effect of soothing irritation, relaxing spasm, and softening the pulse, as James's powder, kermes, ipecacuanha, camphor, antimonial wine, are in fact the best expectorants; inasmuch as they tend more to render the bronchial secretion less tenacious, where it is glutinous and obstructing the bronchi, and to diminish its quantity when too copious, than those which are of a heating or stimulating kind.

104. *b. Amongst* those medicines which are considered as attenuants, deobstruents, and alterants, there are none which possess greater claims to consideration in this disease than the pure *alkalies* and their carbonates, or their combination with oils, and antispasmodic or narcotic substances. However the propriety of applying the above terms to certain medicines in this disease may be cavilled at, there cannot be the smallest doubt, in the minds of those who closely observe the operation of remedies, that certain substances produce effects, on the respiratory surfaces and on their secretions, that justify the use of these terms. The *alkalies* in various forms of combination, but particularly with *oils*, have been much praised by WOLFF, BACHE, SARGONE, MASCAGNI, and LAENNIG. Either in the pure state or in that of carbonates, combined with the oils of *aniseed*, or of *almonds*, with ipecacuanha, small doses of blue pill, and hyoscyamus, the *fixed alkalies* are amongst the best remedies to which we can have recourse, particularly in the catarrhal or bronchial complications, and when the disease is connected, as it very often is, with irritability or other disorder of the digestive organs. I have experienced the greatest service, in practice, from the following, and from Formulæ No. 348. 457.

No. 50. R Sodæ Carbon. exsic. ℥ij.; Pulv. Ipecacuanhæ gr. vj.; Pilul. Hydrarg. gr. vj.; Olei Anisi ℥iij. vel q. s. ut fiant Pilulæ xvij.; quarum sumantur duo, bis terve quotidie.

No. 51. R Potassæ Carbon. ℥ij.; Pilul. Hydrarg. gr. iv.; Extr. Hyoscyami (vel Extr. Papaveris Albi) ℥j.; Olei Amygdal. Dulc. q. s. ut fiant Pilulæ xvij.; quarum capiat binas ter quotidie.

105. Under this head, I may make further mention of the balsams, combined with small doses of rhubarb, or with the addition of magnesia; or of a combination of assafoetida, or myrrh, with galbanum, ipecacuanha, and soap, or the fixed alkalies (F. 503—510.); frictions with stimulating or antispasmodic liniments in the course of the spine (see the LINIMENTS in the Appendix); the nitro-hydrochloric acid wash, in a tepid state,

over the chest, night and morning, or either the one or other only; warm clothing, &c.

106. *C. Blisters, issues, and artificial eruptions* are often extremely beneficial, particularly when asthma has supervened to suppressed discharges, to exanthematous diseases, or in the gouty and rheumatic diathesis. A large blister, applied between the shoulders or on the chest, a smaller one kept open, and issues and setons, have been recommended by the majority of writers. ZACUTUS LUSITANUS and SEVERINUS advise the actual or potential cautery to the nape of the neck. The production of artificial eruptions over the chest by the ointment of the potassio-tartrate of antimony, appears to me, from considerable experience of its effects for many years (see *Lond. Med. Repository*, vol. xvii. p. 302.), preferable to any other mode of counter-irritation in asthma, particularly when the use of it is commenced during the interval.

107. *D. Tonics and astringents.*—*a.* The use of the preparations of bark during the intervals has the support of the best writers on the disease. Amongst these I may notice FLOYER, BANG, CHAPMAN, HEBERDEN, FELDMANN, RANÖE, FRANK, WITHERS, RYAN, BREE, and LAENNEC. The states of the disease in which they recommend it, are, 1st, When the disease assumes a periodic type, or when it is connected with malaria; 2d, In the pituitous form of the disease, when the habit is relaxed and leucophlegmatic; and, 3d, When the stomach is much debilitated. There can be no doubt of the preparations of bark or the sulphate of quinine being indicated in such cases. Indeed, wherever the powers of the constitution require to be rallied, and where there exists no inflammatory irritation to contra-indicate it, bark and other tonics are frequently beneficial. In these cases, the decoction or the infusion may be given, with the liquor ammoniæ acetatis, and vini ipecacuanhæ, or with the carbonates of the alkalies.

108. *b.* I have derived great service from the sulphate and oxide of zinc in the humoral form of asthma, particularly under the circumstances now described. Either of these preparations may be combined with ipecacuanha, camphor, myrrh, hyoscyamus, conium, opium, &c., according to the peculiarities of the case. Where it is desirable to produce a nauseating or emetic operation during the fit, or in anticipation of it, the sulphate of zinc is the next best medicine to ipecacuanha that can be employed.

109. *c.* The preparations of iron have met with the approbation of BREE and STANÖER, particularly the sulphate. It may be employed in similar cases to those for which bark and the sulphate of zinc are prescribed. I can only allude to the recommendation of the mineral acids with opium, by FLOYER, &c.; of the sulphate of barytes, by KECK and HUFELAND; of arsenical fumes, by the Arabian physicians, and EITMULLER; of Fowler's solution, by ALEXANDER; of the nitrate of silver, by ZALONY; and of a solution of phosphorus in ather, by several German writers. These very active medicines are admissible only in the most obstinate cases, particularly when occurring in relaxed or debilitated habits, and when other active tonics and antispasmodics are indicated. *Saint Ignatius's bean*, and the extract of *nux vomica*, have also been mentioned by STEIN and HAHNEMANN. *Strychnine*, the active constituent of these

substances, seems deserving of a fair trial in asthmatic cases.

110. *d. Sulphur and its preparations* have been advised by DIEMERBROECK, GASSER, MARTINS, and BANG; and from a few opportunities which have presented themselves of trying them, I consider them, particularly the *balsamum sulphuris*,—a combination of sulphur with the oils of aniseed, &c. (see F. 21. and 22.),—and the *sulphurets of potassium and sodium*, as medicines of no mean efficacy in several states of the disease. The sulphur precipitatum or sublimatum, taken in the form of an electuary (see F. 82. and 89.), is one of the best aperients to which we can resort in cases of asthma or continued dyspnœa. It may also be taken as follows:—

No. 52. R Sulphur. Præcip. ʒss.; Semin. Anisi contus. ʒijss.; Confect. Semæ et Syr. Tolut. aa ʒvj. M. Capiat coch. ij. minima pro dose.

111. There are various medicines which have been recommended in the paroxysms, which may also be occasionally employed in the interval, particularly shortly before the expected accession of attack, and upon the first intimation of its approach. Of these, the most important are the antispasmodics and narcotics already mentioned (§ 75.), with the smoking of tobacco, stramonium, and aniseed, and the inhalation of the vapours of narcotic substances, and certain gases (§§ 85. 88.).

112. *Flatulence* is a very frequent attendant upon asthmatic cases, chiefly before the invasion of, and during, the attack. It seems connected with irritation of the digestive mucous surface, and deficient vital power. The relief of this symptom is often a matter of importance. For this purpose I have sometimes prescribed the following:—

No. 53. R Olei Anisi ℥ viij.—xij.; Sodæ Carbon. gr. xv.; Sacchari Alb. Magnesiæ Calcinat. aa ʒj.; tere et adde Tinct. Castorei ʒi.; Tinct. Capsici ℥ iv.; Tinct. Sennæ Comp. ʒij.; Aquæ Ment. Virid. et Mist. Camphoræ aa ʒv.; Syrupi Tolutani ʒs. M. Fiat Haustus, ʒiis v. et 4tis horis, ad tertiam aut quartam vicem sumendus.

113. *3d. Of the treatment of the various symptomatic and complicated states of the disease.*—But little is required from me on this subject, after the detailed account of the treatment now given. When the disease is associated with either of the usual forms of *catarrh*, diaphoretics, consisting chiefly of ipecacuanha, antimonials, &c., combined with narcotics or anodynes, are chiefly indicated; and, if inflammatory irritation seems to exist in the bronchial lining, local depletions, colchicum, or digitalis, counter-irritants and revulsants, gentle aperients, and the inhalation of the vapour of warm water, in which a little camphor has been thrown, may be added to the above.

114. In the frequent complications of inflammatory irritation of the digestive mucous surface, and disorder of the biliary apparatus, or of derangement of the functions of the heart, it will generally be advisable to commence the treatment with five grains of blue pill on alternate nights, for three or four times, and with an aperient draught on the following morning. By these the secretions will be excited, and the bowels evacuated. Afterwards the healthy state of action of the capillaries of the mucous surfaces generally will be promoted by exhibiting half a grain of blue pill, three or four times in the twenty-four hours, combined with two or three grains of the extract of hyoscyamus, or of extract of hop; vegetable tonics, with the fixed alkalies, or

other stomaclic medicines, being taken through the day. If we have reason to suspect the existence of organic change within the chest, particularly inflammatory congestion in the lungs, enlargement of the structure of the heart, &c., the insertion of issues, or keeping up an abundant eruption on the external surface of the chest by the tartar emetic ointment, should be added to the above means. This treatment ought, with occasional variation according to the circumstances of the case, to be perseveringly continued for weeks, or even months; and it will often succeed, even in the most unfavourable complications. The *trisnitrate of bismuth*, combined with tonic or bitter extracts, will also be found of service in the gastric associations of the disease.

115. When the disease is associated with affection of the head, or curvature of the spinal column, setons, issues, or moxas in the nape of the neck, or in the course of the spine, may be tried. If it be attended with disease of the liver, external irritation, the nitro-hydrochloric acid bath or lotion, small doses of mercury, and the plaster, Form 117., may be prescribed. Organic lesions of the heart and large vessels, and dropsical effusions, require a combination of these measures with the use of alkalies, digitalis, opiates, &c. When hysteria, and generally increased sensibility and susceptibility, attend the asthmatic affection, tonics with antispasmodics are principally indicated. In the other complications of asthma, the treatment recommended in *Dyspnoea* will be generally appropriate.

116. 4th. *Of the regimenal treatment.*—Much advantage will be derived in asthma from strict attention to diet and regimen,—comprising bathing, exercise, air, and climate, the use of mineral waters, &c. *A. Cold sponging the surface of the chest, and cold bathing,* are amongst the most approved means that can be resorted to during the intervals of asthma. They tend both to diminish the sensibility and susceptibility of the patient to the impression of cold,—one of the most frequent exciting causes of the attack; and to give a salutary tone to the respiratory mucous surfaces and vessels ramified in them; and hence they prove the best means which can be resorted to for the prevention not only of the asthmatic attacks, but of catarrhs, and all other affections and diseases of the respiratory organs. The patient should commence this practice with the following lotion, with which the whole of the chest and upper part of the abdomen should be sponged, or rubbed with a towel or piece of flannel wetted with it, and afterwards be dried, using smart friction at the time:—

No. 54. R. Acidi Acetici Pyrologneivei Vini Albi, Liq. Ammoniac Acetatis, aa ʒijss.; Aq. Rosae ʒv.; Spirit. Vini Tenuioris ʒij. M. Fiat Lottio.

This should be used every morning upon getting out of bed; and if the patient commence with it during the winter, a fire may be kept in the dressing room, and the chill taken off it for the first few days of using it. Instead of the above lotion, a solution of common salt in water, in the proportion of two table-spoonfuls to a pint, or one part of vinegar to two of water, may be employed. After these have been continued for some time, or as long as the patient may please, and the system has been thus prepared for it, the shower-bath may be substituted with advantage,

particularly if the patient be in that state of health which will allow him to bear the shock without risk. Sea or salt water bathing may also be resorted to all the summer and autumn; and the shower bath, or at least cold sponging the surface of the trunk of the body, all the winter and spring; for it will generally be advisable not to discontinue this practice for any considerable time after it has been fully adopted and found of service. In addition to the cold bath, the patient should have recourse to regular exercise in the open air; and attend to the state of his digestive organs, and the regular functions of the bowels.

117. If along with the asthmatic affection the patient have complained of palpitations, irregularity of the action of the heart, oedema of the ankles, severe dyspeptic symptoms, and disorder of the liver or bowels, these ought to be removed, before commencing with cold sponging and bathing, by local depletions when they are indicated; by very small doses of blue pill, or the hydrargyrum cum creta, with the carbonates of the fixed alkalies, and hyoscyamus given at bed-time, a gentle aperient draught the following morning, and bitter tonics, with the alkalies through the day. The recommendation of cold bathing in asthma may startle some; but when all associated disorder of an inflammatory kind has been removed by appropriate treatment, and the means now specified, and when the system has been duly prepared for it, cold bathing is actually one of the most salutary measures, and the most permanently beneficial, that can be prescribed. It has, moreover, received the sanction of *CÆLIUS AURELIANUS*, *FLOYER*, *WITHERS*, *MILLAR*, *RYAN*, *BREE*, and *HUFFELAND*,—names which should claim our respect for whatever they recommend, even if our own experience did not altogether confirm their opinions, which, however, is in accordance with theirs as to this practice.

118. *B. Mineral waters.*—The waters in this country, which are best suited to asthma, are those of Cheltenham and Leamington; and of Buxton and Bath, to some of its complications, particularly the arthritic. *Dr. J. CLARK* very justly remarks (*The Influence of Climate, &c.* 2d ed. Lond. 1830, p. 371. *et seq.*), that when asthma is accompanied with chronic irritation of the bronchial membrane, or with disorder of the digestive organs, and an unhealthy state of the skin, a course of warm mineral waters will often prove of benefit. The springs of Ems on the Rhine, of Carlsbad, of Bonnes and Caunterets in the Pyrenees, and of Mont d'Or in Auvergne, are those chiefly esteemed on the Continent. The great difficulty generally is, that the climate and degree of elevation of these places will often not suit particular asthmatic cases. Where the climate of a valley is likely to suit the patient, Ems and Carlsbad will be preferred; and where an elevated situation is required, the Pyrenees and Mont d'Or will be chosen. The artificial waters of Ems and Carlsbad, prepared at Brighton, are but little inferior to the natural springs. In a case of this disease, where I directed those of Ems, great benefit was obtained from them.

119. *C. Change of air and climate.*—It is impossible to point out the particular climate or locality which will best suit the asthmatic patient; for the state of air or climate which will suit one, will distress another, and without any very evi-

dent cause to explain the different effect. In nearly all cases, however, changes of air are beneficial, chiefly as respects the general health of the patient, and the disorders with which asthma is associated. Upon the whole, a temperate, equable, and moderately moist state of the air is best borne: but even in this, there is much uncertainty. The physician must be guided in his choice by the kind of asthma with which the patient is afflicted, and by the ascertained effects of certain seasons and localities in his particular case. In general, a moist and warm, or mild climate, as the south-west extremity of this island, will suit the spasmodic or dry form of the disease, and that most commonly associated with the dry catarrh, much better than any other in this country; whilst the pituitous or humid variety, occurring in the debilitated or aged, and in those of a relaxed and leucophlegmatic habit, and attended with much expectoration, will require a dry and a somewhat bracing state of the air.

120. *D. Diet.*—Very little is required to be stated on this topic. The food should be always light, digestible, in small quantity, and chiefly farinaceous; particularly in those cases which indicate general or local plethora, inflammatory irritation, and disorder of the digestive organs. FLOYER particularly insisted upon abstinence, as to both eating and drinking; and later writers, and experience, have confirmed the justice of his injunction. When the disease is accompanied with lowered energies of the powers of life generally, the diet should not be so poor as to furnish insufficient means whence the mischief may be repaired; but it ought, notwithstanding, to be light or digestible, and not exceeding the powers of the digestive organs to manage with facility.

ATROPHY.—(From the privative α , and $\tau\rho\phi\acute{\alpha}$, nutrition, or $\tau\rho\phi\acute{\omega}\nu$, I nourish.)—**SYN.** *Atrophie, Consumption*, Fr. *Ungedeiben, Schwindsucht, Auszehrung*, Ger. *Voedeloosheit*, Dut. *Astrofia, Somma Magrezza*, Ital. *Wasting*, Eng. **CLASSIF.**—**PATHOLOGY**—*Morbid Structure.*

1. **DEFIN.** Deficient nutrition of a part or of the whole frame, owing to which its natural dimensions are necessarily reduced.

2. The healthy proportions of the various parts of the frame are preserved by their vital endowment, and are intimately dependent upon the conditions of this influence. When it preserves its due relations throughout the frame, a continued vital attraction of molecules from the blood takes place, to an extent sufficient to supply the place of those particles, which, having lost their vital affinity, are removed by absorption. This slow process, by which animal particles are taken away, for a time, from the current of the circulation, a-similated in the various tissues, afterwards detached from them when they no longer are suited to the purposes of the structure, and carried back to the circulating current to be partly eliminated from the frame, and partly changed into different conditions, is not infrequently liable to be disturbed in some one of its parts or steps. Thus, when the vital influence of an organ, or of the whole frame, is in a state of activity, the attraction of molecules from the blood, similar to those constituting the different tissues, is energetic, and extended to a greater number of such molecules,—they are held in closer affinity, and the bulk of the part is increased. But when the state of the vital endowment is reversed, when it is weak or depressed, this attraction proceeds slowly and languidly, and, the existing affinity being also weak, the molecules composing the tissues are sooner removed by the process of absorption than in health, and the part thus circumstanced is wasted, from a more rapid loss of its molecules than can be supplied by the low state of vital affinity. Thus, as to the former case, a double condition of the organisation, but of opposite natures, actually obtains; namely, the attraction is extended to fewer molecules, and the affinity between them is more languidly exerted, they being more rapidly carried

by the process of absorption, back into the blood, from whence they came, in order to be partly changed and partly eliminated from it; and the part thus affected, instead of retaining its healthy proportions, becomes wasted, deficient in its constituent molecules, or atrophied. Thus we perceive that there is a continued circulation of nutritious particles in the very tissues which they compose; that this circulation, and the affinity which preserves them in their spheres, is vital, influenced by, and fluctuating with, the various conditions of the vital endowment of the frame, the nutrition and bulk of a part being intimately dependent upon it.

3. Nutrition being, then, the result of a vital attraction exerted between the molecules of matter constituting the elementary tissues, and those which are similar to them in the blood, and being co-ordinate with the strength of that attraction, atrophy necessarily proceeds from a diminution of this affinity, and the more rapid transit, consequent upon this diminution, of the particles which have been attracted, back into the current of the circulation. The healthy proportion of the tissues is therefore continued by a due equilibrium being preserved between the attractive influence on the one hand, and the continuance of vital affinity on the other. When either the attraction is active, or its duration long, the bulk of the structures will be increased; but when the former is weak, or the latter of short continuance, atrophy will naturally result.

4. The truth of these propositions is evident from a due consideration of the various phenomena of health and disease, and by the numerous contingent circumstances which influence the conditions of the different structures of the body. At this place I will briefly describe, *first*, the appearances which atrophied structures assume; *secondly*, the various causes and circumstances which, influenced by the vitality of the frame, produce this change; and, *thirdly*, the treatment that may be employed to remove it. Thus I will confine myself, at this place, entirely to the consideration of atrophy, in its *generic* acceptation; the *species* being treated of under distinct and separate heads.

5. *A. States or appearances of atrophied parts.*—Atrophy may be confined to particular structures; it may affect only a particular constituent tissue of an organ, whilst its associated tissues are hypertrophied, and it may extend to various contiguous structures or unconnected organs. A particular constituent tissue may, however, be wasted, and yet its associated structures may be augmented in bulk, as I have shown occasionally to occur, when describing the morbid states of the liver. When this takes place, either no diminution, or an actual increase of the whole organ, is observed. When a compound organ, or part formed of various elementary tissues, is atrophied in all its constituents, the diminution of volume is then very remarkable; although, in some cases, as when the atrophy consists chiefly of a rarefaction of the internal structure of an organ, as of the lungs and bones, the external surface presents little or no change.

6. The earliest and most essential change in an atrophied part is diminution of the quantity of blood sent to it; and next to this, and chiefly owing to it, is greater paleness of colour. Sub-

sequently the organisation is still more completely changed; so much so, frequently, that all traces of its original conformation are lost, and the part is reduced to the state of cellular or fibro-cellular tissue, generally of small size. In some cases, the part is not only extremely atrophied, but at last disappears altogether. When membranous structures are atrophied, they become much thinner and more diaphanous than natural, or even perforated.

7. The atrophy of certain organs or parts is a natural or healthy change, as respects the fœtus in utero, and the newly-born infant. The parts which experience those changes are too well known to require notice. Several structures, especially muscular parts, sometimes have preternatural quantities of fat deposited on their surfaces during the progress of atrophy. This is often observed in respect of the heart, and appears to result from the same causes; namely, diminished vital energy, occasioning insufficient nutrition or assimilation (§§ 2, 3.), and a morbid secretion of fat, which often is as much a consequence of diminished vital energy, as insufficient nutrition of the different structures is the result of this state; both changes being, in some cases, merely grades, in others modifications, of the same vital manifestation.

8. Various parts of the body naturally undergo marked atrophy during advanced age. Of these the most remarkable are the generative organs, particularly the ovaria, mammary glands, testes, the thyroid gland, the bulbs of the hair, adipose tissue, the lungs, and bones. Atrophy of these and other parts has received a more particular notice under their respective heads. I may, however, remark, respecting the atrophy which results from age, that it is very evidently the result of diminished vitality, especially as those parts which first experience a loss or diminution of their functions, either from age or exhaustion, are the first, to be atrophied; and that it often differs from other forms of atrophy, in consisting merely of a deficiency of the fluid constituents of the structures—in a condensation and dying of the organs, and not of a loss of the molecules constituting their solid parts.

9. *B. The secondary causes which, under the influence of the vitality of frame, produce atrophy,* are, 1st, Original deficiency of development, constituting *congenital atrophy*. This state of atrophy may exist in every grade, and may amount to a total absence of an organ or part. When it takes place to this extent, it has evidently arisen from an arrest of the formative process, or of the development of the tissues, in consequence of disease of the embryo. If the disease affect the nervous centres, the parts supplied with nerves from them are sometimes either much atrophied or altogether wanting, as MM. ROSTAN and SERRES have shown. But this is only an occasional occurrence; for parts of the brain or of the spinal chord have merely consisted of a serous sac, and yet the organs of sense and the limbs have been fully developed; and there have occurred many cases in which both brain and spinal chord have been entirely wanting, and yet the nerves proceeding from them and the organs which the nerves supply, have been fully formed; evincing the truth of the doctrine stated by the writer many years since (see *London Med. Repos.* vol. xvii. for May, 1822;

and *Notes to RICHERAND'S Elements of Physiology*, 1st ed. 1824), that the nerves are first formed, and the cerebro-spinal centres subsequently developed.

10. 2d. A diminution of the influence of those nerves which preside over the circulation of a part, and its assimilative and proper functions, rapidly reduces its volume. It is chiefly owing to this cause that the organs of generation waste in old persons. The ganglia which supply these organs, in both sexes, become, in old age, small and indistinct; and the nerves which issue from them to these parts can scarcely be traced. I have no doubt that a similar result follows injury or change of the ganglia or ganglial nerves in other parts of the body. The paralysis attendant upon painters' colic is generally accompanied with great wasting. In cases of unreduced dislocation, when the head of the bone presses upon the nerves, wasting is a frequent consequence, chiefly owing to the incapability of exerting the voluntary muscles, which are rapidly atrophied when they remain inactive. Injuries of nerves, of whatever description, that interfere with their functions, will, as shown by BELL, LORSTEIN, and several others, occasion atrophy. But I may add, that whilst injuries of ganglial nerves will produce it directly, by arresting the nutritive actions, injuries of voluntary nerves occasion it indirectly only, and chiefly by depriving the muscles of their contractile powers, and reducing them to that state of inactivity which is more or less rapidly followed by atrophy. This is proved in the numerous instances which come before us of paralysis originating in the brain. The wasting of the paralysed limb in these cases is seldom great, and it is chiefly limited to the muscles; the other structures, particularly the cellular and adipose, being unaffected.

11. 3d. Diminished supply of blood is a very frequent cause of atrophy. This may be local, as in cases of obliteration of a large arterial trunk, and when the functions of an organ cease. In many such cases, however, the obliteration may be the consequence of injury of the ganglial nerves which supply the artery, or of the cessation of the functions of the part. The general state of atrophy which occurs after tubercular formations in the mesenteric glands, or in the lungs, is generally partly owing to the diminution of the entire mass of blood, together with lowered vital influence; the nutritious molecules, and the assimilating or attractive power being both deficient. A similar inference may also be extended to the wasting accompanying idiopathic anæmia.

12. 4th. When the functions of a part or organ are arrested, atrophy always results. This is remarkably the case in respect of the voluntary muscles (§ 10.). On the other hand, increased function of an organ contributes to augmented volume. The urinary and generative organs furnish well-known proofs of these positions, and illustrate those with which I commenced, namely, that nutrition, and consequently atrophy, most intimately depend upon the states of vital manifestation of an organ or part. Other organs, incapacitated from acting also undergo a marked diminution of their size. Even the lungs, when the principal bronchial tube of one lobe is obstructed, will experience atrophy of that lobe, as MM. REYNAUD and ANDRIAL have shown. In

cases of death from hunger, the stomach and large bowels appear wasted.

13. 5th. Atrophy will also present itself as a consequence of inflammation; and, in some cases, will amount to obliteration or disappearance of the part. Such changes are not infrequent in blood-vessels and excretory ducts. It is sometimes observed in the spleen, liver, and gall-bladder; the last of which has been observed to be wanting or entirely obliterated from this cause. In the majority of such cases, the atrophy has proceeded from obstruction to an artery or vein having occurred during the disease, probably from the extension of inflammation to them, or from the pressure of some of the usual products of the inflammatory state.

14. C. TREATMENT OF atrophy.—In all these circumstances under which atrophy occurs, it will always be observed that the vital energies, in some one or other of its manifestations, are diminished or perverted—most frequently the former. This fact furnishes us with the most rational indication as to the removal of the morbid state which it occasions. Having first ascertained the circumstances and pathological states of the atrophied organ, we are to direct our attention to remove them as far as may be possible. We are next to endeavour to restore the natural vital energy of the organ by exciting its functions, and promoting the constitutional powers. Knowing that, by increasing the natural actions of a part, we thereby increase its nutrition and bulk, we should endeavour to apply this principle to the removal of atrophy, but with a cautious avoidance of fatigue or exhaustion being occasioned by the means we use for this purpose. When the atrophy seems to depend upon the development of tubercles, or upon engorgements of lacteal glands or tumours, pressing upon nerves or large vessels, the preparations of iodine are indicated, on account both of their influence in removing these tumours, and of their excellent tonic powers when judiciously administered. In many cases the functions of the digestive organs—stomach, liver, and bowels—are torpid, and consequently the nutritious fluids are not sufficiently prepared to be assimilated in the different tissues. Healthy chyle is not supplied in the requisite quantity, or, if supplied, is not converted into healthy blood for the nourishment of the structures. In these cases, although the energy of the whole frame is deficient, yet our principal means of medication are to be directed to these organs. (See art. TUBERCULAR CONSUMPTION, MARASMUS, MESENTERIC DISEASE, and TABES DORSALIS.)

AUSCULTATION.—(From *ausculto*, I listen.) CLASSIF.—PATHOLOGY, *Semeiology*.

1. This term is applied to the methods used to ascertain the seat and nature of disease, by the signs which may be recognised by the sense of hearing. It comprises the study of all sounds indicative of disease, whether heard by the unassisted ear, or through the medium of instruments; and whether arising naturally, or produced artificially. The observ-

ations, I have to offer upon this mode of investigating disease may be arranged in the following manner; but I shall confine myself at this place to the consideration of the *first* class of signs, and devote to the *second* class a distinct article. (See PERCUSSION.)

2. I. SIGNS FURNISHED BY SOUNDS PRODUCED NATURALLY WITHIN THE BODY.

A. Sounds having their seat in the chest.—*a.* Depending upon the passage of air during respiration. *b.* Proceeding from the action of the vocal organs. *c.* Depending upon the action of the heart.

B. Sounds having their origin in the arteries.

C. Sounds seated within the abdomen.—*a.* Proceeding from air in the digestive tube. *b.* Depending upon the foetal circulation.

II. SIGNS FURNISHED BY SOUNDS PRODUCED ARTIFICIALLY. (See PERCUSSION.)

3. HIPPOCRATES remarked that the existence of fluids in the thoracic cavity might sometimes be ascertained by applying the ear for some time to the side of the chest; and our countryman HOOK (*Posthumous Works*, p. 39. &c.), in several very pointed observations, not only stated the importance of attending to the sounds produced by the “internal motions and actions of bodies,” but also of rendering them sensible so as to distinguish between them; for the doing of both which, he thinks, “it is not impossible but that in many cases there may be helps found.” M. DOUBLE, also, was in the habit of applying the ear closely to all parts of the chest, in order to examine the signs furnished by the action of the heart, and by respiration; and published his recommendation to cultivate this means of diagnosis, in his able work on Semeiology, two years before the appearance of M. LAENNEC’S celebrated production. Although, therefore, M. LAENNEC may not have been the discoverer of the importance of auscultation in the investigation of disease, yet is he clearly entitled to the honour of discovering *mediate* auscultation—of inventing the stethoscope—and not only of bringing both these modes of examination into general use, but also of strongly recommending percussion, and of improving, in a very remarkable manner, our knowledge of the pathology of pectoral diseases.

4. It is unnecessary to occupy my limits with a description of the instrument termed the *stethoscope*, as its construction, with the improvements of M. Piorry, and the acoustic principles on which it assists the sense of hearing, have been frequently described, and are so simple, as to be readily understood, even by those who are not already acquainted with it. I may remark at this place, that auscultation, like every other method of investigation, requires practice for its perfection. The young practitioner should therefore early commence the study of the sounds of respiration and of circulation, at first with the unaided ear upon the healthy subject, and preferably on children, from five to twelve years of age, as in them all these sounds are distinct, and seldom modified by organic disease. Having made himself familiar with these sounds, by frequent recourse to this practice, he may provide himself with the cylindrical stethoscope in general use, and with the one called Piorry’s; and, with their aid, continue his study of the sound produced within the living body.

5. Having limited myself at this place to the

consideration of the SIGNS FURNISHED BY SOUNDS PRODUCED NATURALLY WITHIN THE BODY, whether heard by the unassisted ear, or by the aid of the stethoscope, I proceed, *first*, to notice the *sounds having their seat in the chest and throat*. These sounds are chiefly produced by the natural movements of the parietes of this cavity and of the organs contained within it, and consist of, 1st, those of respiration; 2d, those of the voice; and 3d, those of the heart. These will be successively considered.

6. I. AUSCULTATION OF RESPIRATION.—*A. Of the healthy and simple respiratory sounds.* The passage of air into, and out of, the lungs occasions a somewhat different sound in various parts of the chest, owing to the difference of size of the tubes through which the air passes. Hence the respiratory sound has one character in the small bronchi and air-cells, another in the large bronchi, and another in the trachea. These sounds have been respectively denominated, by LAENNEC, ANDRAL, and WILLIAMS—the best writers on auscultation—vesicular, bronchial, and tracheal. The *tracheal* sound is heard in the anterior and lateral parts of the neck, the upper portion of the sternum, and the sternal part of the subclavian regions. The *bronchial* respiration is heard in the middle portion of the sternum, and parts of the mammary regions contiguous to it, and in the axillary and interscapular regions. *Vesicular* respiration is perceptible over the remaining parts of the chest in health. These sounds are double; the one being that of inspiration, the other of expiration. The former is much stronger than the latter, which is often scarcely to be heard by the unpractised ear, unless assisted by the stethoscope.

7. It is difficult to describe these sounds with accuracy. The vesicular sound is a dull and diffuse murmur, or a feeble oenathing, resembling that proceeding from the passage of the air through the nostrils in a healthy and quiet sleep. The bronchial respiration is more tubular and blowing, and is chiefly confined in health to the situation of the largest bronchi. The tracheal sound merely conveys the idea of air passing through a tube of larger calibre, and is more hollow and blowing.

8. The respiratory sounds vary in their intensity, not only in different persons, but also in the same person, at different epochs of life, and at various times. The thickness of the parietes of the chest does not materially diminish their intensity; but the activity of the respiratory function affects them most materially; this function presenting different grades of activity in different persons. Dr. WILLIAMS has remarked that they are more distinct after meals and moderate exercise. After excessive exertion they are diminished. Fear, and the depressing passions, have a similar effect.

9. The respiratory sounds are greatly modified by age. From birth to the period of puberty, they are much louder and shriller than in after life, and the whole respiratory function more active. This state of the respiration has been called *puerile* by LAENNEC; and occurs sometimes in adults, either generally or partially, from momentary excitation, or the presence of disease in a part or parts of the lungs. At puberty the respiration is less noisy; and in a few years becomes much deeper, and assumes the adult character.

10. The vesicular sound being the result of the perfect penetration of the air into the lungs, its equal and simple presence is a sign of the healthy performance of the function. But this sound may vary in degree. It may be feeble in all parts, owing to constitutional peculiarity, or only in particular parts, when we should suspect disease; but it is no proof of disease, unless it be associated with certain peculiarities of sound hereafter to be noticed. The total absence of respiratory sound in a part indicates either the exclusion of the air from the part of the pulmonary tissue underneath, or effusion of fluids, or the introduction of air into the pleura. Here we must have recourse to *percussion*, in order to give precision to the information. (See *PERCUSSION*.) In some cases the natural vesicular sound is absent, and a bronchial respiration is heard. In these we must infer that the vesicular murmur is suppressed by a condensation of the pulmonary structure, which, owing to this change, becomes so good a conductor of sound, that the bronchial respiration either becomes louder or is heard in unusual places. In other cases, a sound resembling the tracheal is heard in situations where vesicular respiration alone exists in health. This is caused by the passage of air into an ulcerated cavity or cavern communicating with the bronchi, and from this circumstance is called *cavernous* respiration.

11. *B. Of the morbid respiratory sounds.*—The respiratory sounds are not only varied in degree, but also in *kind*, or they are mixed with different *adventitious* sounds. These variations of *kind* are produced, 1st, by changes in the parietes and vicinity of the tubes, and in their secretions; and, 2d, by morbid states exterior to the pulmonary tissue. Under the first of these are ranked the different *varieties of sound produced by the presence of morbid secretions within the air-tubes, and the lesions producing these secretions.* This class of morbid sounds have been variously denominated. By the French they have been named *râle*; by some of our own writers the word *rattle*, and by Dr JOHNSON the word *wheeze*, have been used. As we have no English term which so fully expresses the idea, to which this morbid sound gives rise, as the word *rhonchus*, adopted by Dr WILLIAMS, and some French pathologists, I shall use it here.

12. *a. Moist crepitous rhonchus, the râle crepitant of LAENNEC, the crepitant rhonchus of Dr WILLIAMS,* has its seat in the air-cells and minute bronchi. It resembles the sound from rubbing a lock of hair between the finger and thumb when held close to the ear; or the crepitation of a piece of lung distended with air when compressed. It is generally uniform, and continues to the end of inspiration, and seems to arise from diminished calibre of the minute bronchi, owing to interstitial effusion, and the admixture of the respired air with the secreted or effused fluids in the air-cells and tubes. It is characteristic of incipient hepatisation of the lungs from pneumonia, and of its resolution; of œdema and apoplexy of the organ; sometimes of early phthisis, of pulmonary catarrh, and bronchitis. But it is only pathognomonic of the first stage of pneumonia; and the more viscid the mucus that is secreted, the more distinct is the crepitant character of the rhonchus. In the

other diseases in which it occurs, the crepitation is less perfect.

13. *b. Dry crepitous rhonchus, the craquement of LAENNEC,* resembles the sound produced by blowing into a dried bladder, and conveys the impression of air distending lungs that have been more or less dried, and whose cells have been unequally, but much dilated. It is only heard during inspiration, and occurs only in pulmonary emphysema.

14. *c. Dry bronchial rhonchus.*—This is either *sibilous*, *râle sibilant* sec; or *sonorous*, *râle sonore* sec, of LAENNEC. The former is a low or loud, shrill or bass, and prolonged *whistle*, such as may be produced by air passing through a small circular aperture, and is owing to some contraction or constriction of the bronchi. The latter is a dull, prolonged, snoring sound; sometimes very loud. It occasionally resembles the bass note of a violoncello, or bassoon, or the buzzing of an insect. It seems to be produced by a flattened contraction in a bronchus of considerable size, leaving very little aperture; and arising from external pressure of the bronchial tube, from local thickening of its mucous lining, or from tenacious mucus within its canal. In a modification of the rhonchus, which Dr WILLIAMS calls the *dry mucous rhonchus*, the sound resembles that of a click-wheel, and is produced by a portion of very adhesive mucus attached to the bronchial lining, which, yielding with a jerking resistance to the air forcing its passage, thereby occasions a ticking sound.

15. *d. The mucous rhonchus, the râle muqueux of LAENNEC, the mucous rhonchus of Dr WILLIAMS,* takes place in the bronchial tubes, and is produced by the passage of air through a thickish fluid, giving rise to a kind of *bubbling* within the air-tubes. It is most frequent in bronchitis and pulmonary catarrh, accompanied with mucous secretion; in hæmoptysis, in phthisis, in pneumonia, and in other diseases which are attended at any period with expectoration. This rhonchus is more gurgling, loud, irregular, and coarse, the larger the bronchi in which it is seated, the bubbles being there larger and more unequal. In the trachea, these characters are particularly marked, and have been denominated *tracheal* from this circumstance, by M. LAENNEC. In the smaller bronchi, on the other hand, this rhonchus is more equal, and its characters less remarkable, the bubbles being of much smaller size. The bubbles producing the mucous rhonchus must necessarily vary in their characters with the varying fluidity of the secretion, and thus the rhonchi will differ accordingly. If the fluid be very thin, the bubbles will be numerous, readily formed, and rapidly break: but if it be viscid, they will be fewer in number, and will often pass along the tubes for some way before they break, the sound being diffused, more regular, and rare. Also the continuance of the rhonchus will be an indication of the quantity of liquid present in the bronchi, as justly remarked by Dr WILLIAMS. If this rhonchus accompany only the first part of inspiration and the end of expiration, the secretion must be scanty. But if the whole of the respiratory act be attended with this sound, then we may conclude that the quantity of fluid is considerable, and extends to the smaller bronchi.

16. *e. The cavernous rhonchus, or gargouille-*

ment, the *mucous rhonchus of morbid excavations* in the lungs, occurs when these cavities contain a fluid, and communicate with the bronchi. It generally exists in the advanced stage of tubercular phthisis, in abscess, and partial gangrene of the lungs. This rhonchus is characterised by a strongly marked mucous gurgling or bubbling sound, confined to a small spot and determinate situation, and is particularly marked upon the patient taking a full inspiration, or after coughing.

17. It may be remarked that this *class* of morbid respiratory sounds — proceeding from changes in the parietes of the tubes, and in their secretions — will sometimes be more or less obscurely heard through effusions in the pleura, when not very large. I proceed to consider the *second class* of morbid sounds, or those arising from lesions exterior to the pulmonary tissue.

18. *a. Metallic resonance, tintement métallique* of LAENNEC, is observed only when a quantity of air is accumulated in the pleural cavity, as in pneumothorax; or rarely in cases where very large tubercular excavations are formed in the lungs. It is most commonly heard when both air and fluid are effused in the pleural cavity, and when there is a communication between this cavity and the bronchi. It is most distinctly heard upon coughing. LAENNEC has distinguished two varieties of this sound, namely, *metallic tinkling*, and *amphoric buzzing or resonance*. These sounds are occasioned by the impulse given to the air accumulated in the pleura, by the vibrations of air rushing through a fistulous opening in the pulmonary pleura, or striking against a condensed part of the pulmonary tissue, or of the pleura itself.

19. *b. Rubbing sound, the sound of friction, the bruit de frottement ascendant et descendant* of LAENNEC. This sound has been particularly investigated by MM. HONORÉ and REYNAUD. It is an obscure, dull sound, perfectly distinct from the respiratory sounds, but synchronous with the motions of the parietes of the chest during inspiration and expiration, and resembling that produced by the rubbing of two soft and somewhat rough bodies on each other. It is loudest, or only heard during inspiration. It is sometimes present in interlobular emphysema, but is more frequently and sensibly heard in pleuritis, with partial albuminous exudation, and with little or no effusion of serum.

20. II. AUSCULTATION OF THE VOICE. — The voice, although produced chiefly in the larynx, has its sound partially propagated inwards by the air in the trachea and bronchi, occasioning, in the smaller ramifications of the latter, a vibratory sensation or fremitus, rather than a distinct sound to the ear through the stethoscope; but, in persons with a large chest and strong voice, a more distinct vocal resonance. When the instrument is applied in the situation of the larger bronchi, as between the scapulæ and under the axillæ, the voice is heard much more distinctly, and the articulation may even be distinguished; but the sound does not seem to enter the cylinder, or to traverse its tube. If we place the stethoscope on the trachea or larynx, when the patient is speaking, we hear the whole of the words, loudly and articulately, and as if passing through the instrument to the ear. These sounds have been called, from their site, *bronchophony* and *laryngophony*; and

arise from the vibrations propagated through the air contained in the trachea and bronchi, and which become weaker as they extend in the direction of the air-cells.

21. The degree of vocal resonance in the chest differs in different persons. It is loudest and most extensive in those who are thin, and have a strong, sharp, treble voice; so that natural bronchophony will extend further in young subjects and in females, particularly through the upper regions of the chest. In fat persons with a deep voice, the natural bronchophony is confined and obscure, especially during the deeper notes. In all the lower parts of the thorax, particularly during the deep tones of the voice, there is either no resonance, or merely a slight thrill or vibratory fremitus, which may likewise be felt upon applying the hand to its parietes. Such are the healthy sounds of the voice in different parts of the chest; but in certain states of disease they are very materially altered, and both the *bronchial* and *laryngeal* sounds are developed in places where they never exist in health. Of the various manifestations of these sounds in disease, I now proceed to take a brief notice.

22. *a. Bronchophony* is developed in disease by the same causes that render the bronchial respiration audible, viz. condensation of the substance of the lungs in the vicinity of large bronchial tubes, without diminishing their calibres, as in hepatisation or induration from the formation of tubercular matter. From this circumstance bronchophony is an important symptom in pneumonia and phthisis. When the condensation is seated near the surface of the upper portions of the lung, and near a large bronchus, the sound may nearly approach laryngophony. The bronchial respiration is generally present with bronchophony, excepting when the hepatisation is extensive.

23. *b. Ægophony* (from *αἴξ*, *αἴγος*, a goat, the sound resembling the cry of this animal,) is merely a modification of bronchophony; and occurs when, with the circumstances which produce it, there are superadded the existence of a thin layer of fluid between the surface of the lungs and the pleura costalis. The bleating sound of the voice to which the term ægophony has been applied is variously modified in different persons, according to the natural tone of their voice, and the different modifications of the diseases which produce it; thus it will resemble the squeaking of Punch; or possess a shriller or sharper key, and sound more like the echo of the patient's voice than the voice itself. Ægophony only exists in pleurisy or slight hydrothorax, when the quantity of fluid effused is no more than forms a thin layer between the lungs and parietes of the chest. LAENNEC states that he has found this symptom present in almost every case of pleurisy; and considers it to be owing to the natural resonance of the voice in the bronchial tubes, rendered more distinct by the compression of the pulmonary texture, and modified by its transmission through a thin layer of fluid in a state of vibration. Dr. WILLIAMS ascribes it to "the successive undulations of the liquid, the result of an irregular transmission of the sonorous vibrations." Ægophony often co-exists with bronchophony, and the one passes into the other.

24. *c. Pectoriloquy.*—The existence, in disease, of vocal resonance in any part of the chest, to the extent of laryngophony, has been termed *pectoriloquy* by LAENNEC. It may be either *imperfect* or *perfect*. It is the result of a morbid cavity, formed in the substance of the lungs, and communicating with the bronchi; to which cavity the sound of the voice, or vibrations of the air in the tubes, is propagated. When the stethoscope is applied to a part of the chest, under which one of these cavities is situated, the words which the patient utters seem to proceed from that spot; and hence the term *pectoriloquy*. “The distinction between perfect and imperfect pectoriloquy is, as in the case of natural resonance, whether the voice seems to traverse the tube, or remain at the end; and the physical difference producing the two modifications consists in the size and situation of the cavity. The most perfect pectoriloquy is produced in cavities of moderate size, which are situated near the surface of the lung, and freely communicate with a large bronchial tube. If the cavity be deep-seated, or if its communication with the bronchi be imperfect, the resonance of the voice will not amount to perfect pectoriloquy. True pectoriloquy produced by a cavity, is generally abruptly circumscribed, so that its limits can be distinctly traced.”—(WILLIAMS'S *Rational Exposition*, &c. p. 43.). ANDRAL appears to be correct in considering perfect pectoriloquy as not common, and that the imperfect state of this sound, or bronchophony, is very frequently mistaken for it. When present in any part of the chest where there is naturally no bronchial resonance, it may be considered as a certain indication of the existence of a morbid cavity, generally tubercular; and when heard in situations of natural bronchial resonance, although more doubtful, yet, if it be perfect, distinctly circumscribed, and heard on one side only, the same conclusion must be come to. It may be further added, that an empty state of the cavity, its rounded and regular shape, and natural sharpness of the voice, particularly in women and children, tend to render pectoriloquy perfect.

25. III. AUSCULTATION OF THE HEART.—A. *In its healthy state.* I have always viewed LAENNEC'S explanation of the sounds proceeding from the heart's contractions as the most defective part of the exposition of his system; and a similar opinion seems to have been entertained by Mr. TURNER, Dr. WILLIAMS, and several others. The observations of Mr. TURNER, and of Drs. STOKES and CORRIGAN, first shook the stability of the views of LAENNEC on this subject; and the recently published researches of Dr. HOPE have almost altogether overthrown them. As I consider the exposition of the actions and sounds of the heart, given in Dr. HOPE'S work, to be the most accurate, I shall follow it on this occasion.

26. 1st. *Of the Contractions of the Heart in the order of their occurrence, &c.*—The first motion of the heart following the interval of repose, is the systole of the auricle. It is a very brief and slight contractile movement, most considerable in the auricular appendix, and propagated toward the ventricle, in the systole of which it terminates, by a nearly continuous action. The systole of the ventricle commences suddenly and diminishes considerably the volume of the organ. “Synchroous with the systole are the first sound, the impulse of the apex against the ribs, and the

pulse of the vessels near the heart;” the pulse at the radial arteries following at a barely appreciable interval. The diastole of the ventricles follows their systole; and these compartments return, by an instantaneous expansive movement, to the same state as during the previous interval of repose. The diastole is accompanied with the second sound, with a rush of blood from the auricle, by a contractile motion of this cavity most observable at its sinus, and by a retrocession of the apex of the heart from the ribs. “Next succeeds the interval of repose, during which the ventricles remain at rest in a state of fullness, though not of distension, through the whole period intervening between the second and the first sounds; but the auricle remains at rest during the first portion only of that period, the remainder being occupied by its next contraction, with which recommences the series of actions described.”—(HOPE on the Dis. of the Heart, &c. p. 40.)

27. The *rhythm* of the heart, or the duration of the several parts of this series of actions, constituting what may be called a beat, is the same as described by LAENNEC:—1st, The ventricular systole occupies half the time of a whole beat; 2d, The ventricular diastole occupies a fourth, or at most a third; 3d, The interval of ventricular repose occupies a fourth, or rather less, during the latter half of which the auricular systole takes place.

28. 2d. *Causes and mechanism of the motion.*—The auricles, being always in a state of fullness, arrive, during the first half of the period of repose of the ventricles, at a state of distension, on which they react and propel a small additional quantity of blood into the full but not yet distended ventricles, in order to bring them to this state, and to cause them to react, and thus expel a greater or less portion of their contents. During the expulsion of the contents of the ventricles, Dr. HOPE considers that the apex of the heart is tilted upwards and forwards, and occasions the impulse against the ribs, in consequence of the retraction of the ventricles upon their base, and on the auricles, which, being in a state of extreme distension, serve as a fulcrum beneath them. The *diastole* of the ventricles appears to be occasioned, 1st, by the relaxation of the principal part of their muscular structure, assisted by an elastic property; 2d, by the distension of the auricles, which has arrived at its height, and brings into action certain layers of ventricular fibres having a powerful influence in distending these cavities; 3d, by the width of the auriculo-ventricular opening, which allows the blood to rush instantaneously, and with facility, from the auricles into the ventricles. The blood expelled from the former cavities into the latter being instantly replaced from the *vena cava*, distension of the auricles immediately recurs, and the same series of actions is continued.

29. 3d. *Causes of the sounds.*—There can be no doubt that the sounds of the heart's actions are not produced by the mere contraction of its muscular structure. To what other cause can we impute them? I conceive that they can only be referred to the action of the parietes of the cavities on the fluid circulating through them, and to the motions of this fluid. According to this view, which has been very diligently investi-

gated by Dr. HOPE, the systole of the ventricle is the cause of the first sound, by the impulse it communicates to the blood, and the diastole of the ventricle is the cause of the second sound; owing, in the opinion of this writer, to the rush of blood from the auricles, produced as already explained (§ 26.), and the succession of the stream against the walls of the ventricle, when abruptly arrested by the completion of the diastole.

30. I consider that it is clearly made out, 1st, That the impulse, the pulse, and the first sound, coincide; 2d, That the ventricle is concerned in the production of the second sound, although the exact manner in which the motions of the ventricle and this sound are connected has not yet been conclusively ascertained; and, 3d, That the actions of the auricles are insufficient to produce either impulse or sound, and that neither the one nor the other result from them. With respect to the production of the second sound, I think that the opinions of Mr. TURNER, Dr. CORRIGAN, and Dr. WILLIAMS, are untenable, and therefore may not be stated; and that the explanation of Dr. HOPE requires further confirmation. From the third of these facts I believe that it may be legitimately inferred, that the physical signs of disease of the auricles are very imperfect, and therefore uncertain.

31. *B. Auscultation of the morbid sounds and impulse of the heart.* — 1st, *Of the impulse of the heart.* Although, strictly speaking, the sounds of this organ are the only objects of auscultation, yet, as the impulse or shock it communicates to a part of the chest is usually made a matter of inquiry, although by a different sense, during the time that auscultation is being performed, I will briefly notice it at this place. The impulse necessarily varies, even in health, in different persons, with the state of the heart's action, and the habit of body. It is also greatly modified by mental emotions, and by various affections of the digestive and other organs. It is always synchronous with the first sound of the heart; but, in rare cases, a slight second impulse also accompanies the second sound; but this is felt deeper in the chest; is more of an obscure tremor, much slighter in degree than the chief impulse or shock, and is only met with in cases of hypertrophy with dilatation.

32. When the impulse is prolonged, strong, and characterised by an extensive heaving movement, thickening of the walls of the ventricles may be inferred. It should, however, be recollected, that whatever excites the feelings of the mind, or hurries the circulation, will occasion a strong impulse; but, in such cases, the actions of the heart are also unusually frequent. *Morbid impulse of the heart* is present in the states of both mental and corporeal repose, and is often unconnected with increased frequency, as in hypertrophy of the ventricles.

33. The impulse may be diminished, even in health, as by the depressing passions. It is often constitutionally so small in amount, as scarcely to be felt. It is also lowered by diseases of remote organs, as diarrhoea, &c., and by abstinence and blood-letting, and whatever depresses the energies of the system. It is generally weak in congestion of the cavities of the heart, in cases of thinning of their parietes, in the asthmatic paroxysm, in

congestion of the lungs, in some cases of pneumonia, and in the advanced states of various diseases; and it may even, although very rarely, accompany certain states of hypertrophy of the heart, particularly during the operation of debilitating causes.

34. In health, the impulse is usually limited to the immediate region of the heart, and chiefly in the situation of the cartilages of the fourth, fifth, sixth, and seventh ribs. Its sphere is extended by increased action of the organ, whether the result of mental or corporeal excitement or of disease; by hypertrophy, and by certain organic changes of organs in the immediate vicinity. When the muscular parietes of the heart are increased without any dilatation of the cavities, the sphere of impulse is not extended far beyond its healthy site; but when dilatation is combined with hypertrophy, the impulse may often be felt on the right side of the sternum, below the clavicles, and even on the back. Diseases of adjoining organs, as hepatisation of parts of the lungs in the vicinity, effusions of fluids in the pleural or pericardiac cavities, tumours in the mediastinum, close adhesions of the lungs to the costal pleura, adhesion of the pericardium to the heart, displacement of the heart, and even an enlarged liver or spleen — when rising into the thoracic cavity, and pressing the diaphragm upon the pericardium — will extend, often to a considerable distance, the impulse of the heart, owing to the increased density of parts which receive the shock. Much discussion has arisen as to the manner in which the heart's shock is produced. Further than that it is occasioned by the muscular actions of the organ, I believe that the phenomenon has not been satisfactorily explained, at least in such a way as accords with the various conditions it presents in health and disease. The explanation given by Dr. HOPE has been already stated (§ 28.).

35. 2d. *Of the changes produced in the natural sounds of the heart by disease.* — The sounds of the heart vary in different persons, even in health. In some they are loud and distinct; in others, the reverse: they may also be dull or clear, in respect of their key. They are generally distinctly heard by the unaided ear, but more accurately by the stethoscope. The impulse and sound are never both present in health, to a great degree, as they depend upon opposite conditions of the ventricles; the impulse being great in proportion to the thickness of the parietes of the ventricles, the sound to their thinness. The sounds of the left side of the heart are strongest at the junction of the cartilages of the left fourth, fifth, sixth, and seventh ribs, with the sternum: those of the right side, under the sternum, and towards its right edge. The sphere of the heart's sounds is, in a very few persons, nearly limited to the sphere of impulse; but it is generally far more extended, even in health. It should not be overlooked, that the sphere of sound is much larger in children and young persons, in females, in the lean, and in those who have narrow or small chests; whereas, in persons whose thoracic cavity is large, and its parietes thick, muscular, or fat, the sound is heard much less extensively.

36. The sphere and loudness of the heart's sounds are increased by the same moral, physical, and morbid causes, which have been stated to

augment its impulse (§ 31.). Therefore, when frequency of pulse accompanies increase of sound, no actual disease may exist; but when a natural or slow state of the pulse is attended with an augmented range of sound, disease may be much more certainly anticipated. The circumstance of the sphere of sound being extended by the organic lesions already noticed as conveying the impulse of the heart (§ 34.), and by tuberculous excavations in the lungs, should not be overlooked. In taking account of the heart's sounds, we should also be aware that the sounds of respiration will occasionally mask them, as the heaving of the chest during inspiration will, in a slight degree, mask some of the shocks of the heart. Generally, the sounds of the heart are strongest in the left anterior part of the chest; and progressively weaker in the sternal, in the right anterior, the left posterior, and in the right posterior parts successively. If this succession be deviated from, or in any way altered, disease exists; and the degree, state, and order of deviation, become signs of some importance. It has been remarked by LAENNEC, that, when the sounds are heard beyond the healthy sphere, in persons with the chest well formed, and presenting none of the causes alluded to as giving rise to such extensive range, these persons will be found to be subject to palpitations, to shortness of breath upon the slightest exertion, to attacks of asthma, and to congestions of the internal viscera.

37. 3d. *Of the adventitious sounds of the heart.* — The sounds of the heart may not only be changed in degree, in extent of sphere, and in the succession of intensity, but entirely new sounds may be superadded. The most common of these are the bellows-sound (*bruit de soufflet*), the saw-sound (*bruit de scie*), and the rasp-sound (*bruit de râpe*). These may either take the place of the natural sounds, or may be conjoined or superadded to them; and they may be present with either the first or second sound, or with both. The bellows-sound resembles the puffing of a pair of bellows, and conveys the idea of smoothness. The saw and rasp sounds are so named from their similarity to the sounds occasioned by the sawing or rasping of wood, and convey the idea of roughness. But the bellows-sound may insensibly pass into the others; and they all vary greatly in loudness. They may occupy the place of the first or the second of the heart's natural sounds, but more frequently that of the first than of the second. The saw and rasp sounds are generally louder, and present a wider range of intensity than the bellows-sound, which is more closely limited to the part which occasions it. They may all be heard in arteries at a distance from the heart, more particularly the bellows-sound; and often when they do not exist in the region of the heart. When the saw-sound proceeds from the heart, it may generally be traced along the arch of the aorta to the subclavian and carotid arteries.

38. The causes of these sounds, and the exact site of the changes which produce them, are obviously the important considerations attached to them. They have been accounted for in various ways, even by their eminent discoverer; and, in general terms, they may be said to arise from unnatural or morbid motions induced in the current of blood circulating through the heart, in-

stead of those natural motions which contribute to the healthy sounds of the organ. Hence, whatever produces the morbid change of the motions of the fluid, will occasion the adventitious sounds; and we have reason to infer that such change is produced either by a permanent alteration of the apertures and canals through which the blood is propelled, or by a spasmodic or nervous state of the same parts.

39. The simple bellows-sound is more common, and arises from slighter changes than the saw or rasp sounds, and is less to be depended upon in diagnosis. Pressure on an artery will occasion it; and when present in the heart, it will sometimes be removed by blood-letting. When even existing permanently, although it is a very strong indication of organic change in the heart, it cannot be implicitly relied on; but when only occasionally present, although such change may be its cause, yet it deserves no reliance. The saw or rasp sounds are much less frequent than the other; are much more constantly found in connection with contracted orifices of the heart; and are very frequently indications of an increased degree of the same causes that produce the bellows-sound. It may, however, be generally inferred, 1st, That these sounds arise from some change in the orifices of the heart's cavities, produced by nervous or temporary causes, or by alteration of structure; more frequently the latter. 2d, That these sounds, therefore, although they indicate the existence of organic disease, are not conclusive evidence of it, as they sometimes arise from other causes. 3d, That in proportion as these sounds possess more of the rasping character, the greater is the probability of organic change. 4th, If the sounds disappear after depletions, upon repose, or without sufficient reason, their dependence upon functional disturbance may be inferred, although not implicitly relied on; their continued absence, however, strengthening the conclusion. 5th, The continuance of these sounds, notwithstanding the means now mentioned, or their diminution merely, is nearly conclusive of organic change. 6th, Intensity of the sounds is no indication of the degree of valvular disease, or extent of the contraction of an orifice; as they may be weak, when these organic changes are extreme. A moderate contraction and size of current seem to be requisite to their full production. The relation of these sounds to the particular changes which occasion them is considered in connection with these changes. (See HEART — Diseases of.)

40. The rasp and saw sounds are often accompanied with a phenomenon resembling a species of impulse, and which can be estimated by the sense of touch only. This is the *thrill* or *purring tremor*, termed "*bruissement*" by CORVISART, and "*frémissement cataire*" by LAENNEC, which is felt when the fingers are placed upon the heart, or on an artery. When existing in the heart, the feeling excited upon applying the hand to the region of this organ, is analogous to the sensation occasioned by the saw or rasp sounds. The fact is, that the same pathological condition gives rise merely to modified sensations as perceived by the medium of different organs, the object exciting the sensations being one and the same; the only difference being that a stronger current is required to produce the pur-

ring tremor, than is necessary to the production of the sounds. It is owing to this circumstance that it is strongest in hypertrophy of the ventricle, or when the circulation is hurried. A firm pressure of the hand on the region of the heart is necessary to feel it well; and a moderate pressure to feel it in the arteries.

41. The last adventitious sound that I have to notice is that which LAENNEC has termed the "*cri du cuir*," and which resembles the creaking of the leather of a new saddle. It seems to be chiefly observed in cases of pericarditis, when the opposing surfaces of the pericardium lose their lubricity, and when they are rendered rough by the exudation of coagulable albumen, or are in an unusual state of dryness; and to be occasioned either by their friction whilst in this state, or by the motions produced in that part of the pericardium reflected over the heart during the systoles and diastoles of the ventricles.

It is unnecessary to add any thing at this place, to what has been stated respecting the auscultatory signs in *diseases of arteries*, and particularly of the *aorta*. The employment of *auscultation of the abdomen*, in order to ascertain the existence of pregnancy, is comprised in the article PREGNANCY.

BARBIERS. — CLASSIF. 4. *Class*, Nervous Diseases; 3. *Order*, Affecting the Muscles (*Good*). I. CLASS, V. ORDER (*Author*).

I. DEFIN. Tremor, with pricking formicative pain; numbness of the extremities, principally of the lower, followed by contractions and paralysis of the limbs, inarticulation or hoarseness of voice, emaciation, and sinking of all the vital powers.

2. This disease has been described by various authors since the appearance of the work of BONTIUS. But we have had no satisfactory account of it until Mr. MARSHALL furnished it in his interesting work on the diseases of Ceylon, and distinguished it from *Berberi*, with which it had been confounded by BONTIUS, and recently by Dr. GOOD. Dr. J. CLARK had, however, noticed it briefly as a distinct disease, many years previously; and the definitions of it given by SAUVAGES, LINNÆUS, SAGAR, and AIKIN, seem to indicate that they were not altogether unacquainted with its nature. I shall here follow the accounts of it by Dr. CLARK and Mr. MARSHALL, as they seem to be the most precise, and to have been the result of much experience.

3. I. SYMPTOMS. — The disease generally commences with a formicative pricking pain in the muscles of the lower extremities, with numbness, tremors, and an imperfect command of the powers of locomotion. Both lower limbs are always

equally affected. In some cases the forearms and hands, and the powers of articulation, are subsequently similarly seized. As the disease advances, the patient is unable to walk steadily. Standing or walking aggravates the uneasiness of the limbs, and either is impossible without support. The superior extremities become incapable of performing their usual offices; and want of sound sleep, great sluggishness, and inactivity, are complained of. The limbs afterwards are deprived of all feeling, and lose their natural temperature; the extensor muscles become quite paralytic, and the limbs contracted. Loss of appetite, indigestion, emaciation, &c. soon follow, and the pulse gradually sinks to a frequent, thready, or fluttering state; all the vital powers become depressed, and death supervenes. As respects its duration, it may be protracted for many months, and it may present various grades of severity. Its forms are frequently more mild, the above description applying to the severer cases. The diagnosis of barbers is described in the article BERBERI, to which disease it is closely allied, and with which it may be associated.

4. Mr. MARSHALL observed many cases of this disease, in 1812, amongst the Caffres composing the 4th Ceylon Regiment. He never noticed it amongst the indigenous inhabitants of this island; and, from every information he could collect, it was only known amongst Africans who had arrived in the island; and he believed that late comers were more disposed to it than acclimated residents. Mr. MARSHALL also met with it in Europeans in Ceylon: and he has observed an analogous affection in horses and dogs; from which, however, he never knew them to recover.

5. Dr. LIND states that barbers is a species of palsy frequent in India, affecting chiefly the lower classes of Europeans, who frequently sleep, when intoxicated, in the open air, exposed to the land winds; and that its attack is sudden, depriving the limbs of motion, &c. It appears also to prevail in Java. Dr. BOSTOCK has described a case which seems to be nearly allied to this affection: and I have been occasionally consulted by patients, whose complaints were very nearly the same as those now described; and who have been seen by several medical men. A very remarkable and extreme case of it, in a gentleman from Jamaica, was lately attended by Dr. ROSCOE and the author.

6. II. THE REMOTE CAUSES of this affection are cold and moisture applied to the body; intoxication, irregularities, and excesses consequent upon inebriety; violent exercise in the sun; lying down in the open air during the heat of the day; exposure to the cold chilling dews of the night, or sleeping when thus exposed; suddenly obstructed perspiration, by currents of air; long fasting, and whatever exhausts the energies of life. The translator of BONTIUS's work states that barbers is frequent on the Malabar coast, where it attacks those who unwarily sleep exposed to the land winds, particularly in the months of January, February, and March; and that it is seldom cured till after the shifting of the monsoon, unless the patient changes the climate.

7. III. TREATMENT. — This affection appears to originate in depressing and debilitating causes; to be characterised by a gradual and chronic sinking of the nervous energy; and therefore to require

a tonic, restorative, and stimulating treatment. Frictions, with stimulating liniments along the course of the spine, and on the limbs; attention to the due performance of the secreting and excreting functions; tonics, combined with warm earliacs, gentle aperients, and antispasmodics; vesication; stinging with nettles; electricity, the internal use of the extract of *nux vomica*, or of strychnine; the application of external warmth, and the use of warm clothing; a nourishing and digestible diet; regular habits, and change to a healthy air or locality; are the chief means of cure. Dr. JOHN CLARK states, that the few Europeans whom he saw ill with this disease were cured by a change of climate, and a sea voyage. In other respects the treatment is the same as that recommended in the article PALSY, particularly palsy from lead. (See COLIC — *from Lead*, and PALSIV.)

CLASSIF. 4. Class, Diseases of the Nervous Function; 3. Order, Affecting the Muscles (Good). I. CLASS, V. ORDER (Author).

1. DEFIN. *Oppressed breathing; paralytic weakness, numbness, and stiffness of the lower extremities; general œdema, with a swollen and bloated countenance.*

2. I. SYMPTOMS.—i. The attack is in some cases gradual; in others sudden and severe. When it is the former, which is more commonly the case, the patient complains for several days of weakness, and inability or unwillingness to exert himself. To these feelings, pain, numbness, and stiffness of the lower extremities, accompanied with œdema; muscular weakness, and dyspnœa, particularly upon motion; a feeling of numbness, fulness, oppression, and weight at the scrobiculus cordis; extension of the œdema over the body, and leucophlegmatic tumescence of the countenance, supervene. As the disease advances, the dyspnœa increases, and the face is more swollen and bloated. The lips, which were at first pale, become bluish and livid; and the lower extremities more numb and feeble, or even paralytic. The stomach is often irritable, especially in the advanced stages of the disease, when it often rejects all ingesta; the bowels constipated; the urine scanty, high-coloured, and sometimes almost suppressed; the pulse is at first either more or less quick, small, and hard, or but little affected; subsequently irregular or intermittent; and the dyspnœa at last becomes distressing and attended with great anxiety, and sometimes with a peculiar fluttering about the heart, and sinking or leipothymia, succeeded by palpitations. In the more advanced stages of the disease the patient cannot lie down; his sleep is uneasy, interrupted, and always unquiet; and the recumbent posture induces violent palpitations, sense of suffocation, and anxiety. The oppression at the præcordia and weight at the scrobiculus cordis increase, and are attended with spasms of the muscles of the thorax and abdomen; the countenance becomes livid, and the extremities

cold; vomiting is either frequent or nearly incessant; the pulse sinks, and the patient dies nearly in a state of suffocation.

3. In this, the most common form of the disease, it usually runs its course in about three weeks or a month; but sometimes, in slighter cases, the patient experiences several relapses, and is at last carried off unexpectedly, when the anasarca symptoms have nearly disappeared, and he has been judged convalescent. In some of the milder attacks, several of the above symptoms are extremely slight, and the disease is altogether of much longer duration, or consists apparently of several distinct seizures. Such seem to have been the form of the majority of cases which Mr. MARSHALL has given in his work. In the most sudden and severe attacks, however, the pain, numbness, stiffness, and œdema of the lower extremities; the dyspnœa and anxiety, and all the more urgent symptoms, are either present from nearly the commencement, or they rapidly supervene to each other, and the patient dies in a few hours, or in a day or two. Such cases appear to be not so frequent as those which are more mild.

4. ii. *Appearances on dissection.*—There is always a leucophlegmatic appearance of the surface, with œdematous effusion to a greater or less extent in the sub-cutaneous cellular tissue, and paleness of the muscles; sometimes with a watery obesity and deposition of fat in the abdominal regions. Occasionally there is fluid effused between the membranes of the brain, and in the ventricles; with vascularity of the encephalon, and slight appearances of congestion in the spinal canal. Serum is always found effused in the pleural cavity, and very frequently in the pericardium. The lungs are gorged with dark blood, and their structure more or less œdematous. Old cellular adhesions are sometimes found connecting the opposite surfaces of the pleuræ. The heart is generally soft, enlarged, and flabby. The peritoneal sac often contains much serum; and the liver is always found engorged with dark blood, is unusually large, and of a very deep colour. The spleen is generally very soft, large, and is, as well as the large veins, loaded with black blood. Sometimes inflammatory appearances are observed in the diaphragm and serous surfaces; but these are only occasionally and very loosely noticed. (CHRISTIE, ROGERS, MARSHALL, and HAMILTON.)

5. II. DIAGNOSIS.—The paralytic symptoms, constant dyspnœa, universal œdema, and leucophlegmatic intumescence of the countenance, characterise this disease sufficiently, and distinguish it from the *cachexia Africana*, with which it has been considered as being allied. (See CACHEXY — *Africana*.) It has been, however, more commonly confounded with *barbiers*; but the history of both diseases shows various differences between them. *Barbiers* is a chronic disease, in which the paralysis, tremors, spasms, and contractions of the limbs, and emaciation, are the most remarkable symptoms; whilst the present malady is acute, often of very short duration, and is characterised by general œdema, dyspnœa, the suddenness of its fatal termination, and the frequency of its occurrence. The former seems to be a species of *paralysis*; and the latter to be a form of *acute dropsy*, very generally diffused throughout the body, and complicated with paralytic symptoms. But it must be admitted that the one is often associated with the other, either of them

being the primary affection. Mr. MALCOLMSON, who has had extensive experience of both forms of disease, states that cases commencing in the form of *barbiers*, often suddenly take on the more fatal and acute form of *beriberi*; and that the latter frequently present the symptoms characteristic of the former. He further remarks, that the two classes of cases prevail in the same places, seasons, and circumstances, and require the same remedies.

6. III. CAUSES.—This disease is nearly peculiar to India, and is most prevalent in various parts of Ceylon, on the Malabar coast, and in that tract of country which extends from Madras to Ganjam; being, according to Mr. HAMILTON, confined to these parts, and extending no further inland than forty miles. It is most prevalent during the decline of one monsoon and the setting in of another, when the air is damp, cold, and loaded with vapours, and the vicissitudes of temperature greatest. Captain PERCIVAL, in his "History of Ceylon," ascribes it to low diet and bad water, and partly to the dampness of the climate. Mr. RIDLEY, however, states that the worst cases he had of it at Trincomalee, where it was remarkably prevalent, occurred during the change from wet to dry weather, when a strong and hot land wind prevailed; and that its severest prevalence at Pulitooané was during dry weather. In the Indian peninsula it seldom extends further inland than sixty miles; but in Ceylon, particularly at Kandy, it has prevailed under very different circumstances, as respects season, states of atmosphere, and topography. It seems to have been much more prevalent in particular districts, where it may be said to be endemic, in one year than in another; and to have assumed, at distant periods, a nearly epidemic form. Dr. CHRISTIE states, that a residence of several months in the district where it prevails is necessary to its production; and Dr. ROGERS never observed it in any person who had not resided six months or upwards in Ceylon. Dr. HUNTER has met with it also in Indian seamen, particularly Lascars, after exposure to a moist and variable atmosphere and privations of food.

7. Opinions respecting both the remote and proximate causes of the disease differ very materially among those who have had opportunities of observing it. Mr. DICK found it most prevalent amongst soldiers who had taken much mercury for venereal complaints, and who were addicted to spirituous liquors. He never met with it in the officers. Mr. RIDLEY, on the other hand, states, that, in 1804, "both officers and privates fell victims to it." Drs. CHRISTIE and ROGERS view it as a consequence of deficient and poor diet, impure and moist air, and of prolonged exposure to marsh exhalations; and consequently as a disease of debility,—an opinion which is in accordance with that of Mr. DICK and Mr. RIDLEY. Mr. COLQUHOUN found it to prevail notwithstanding prophylactic measures founded on these views; and Mr. MARSHALL did not observe it to occur amongst the troops in Ceylon, when exposed to the causes to which Drs. CHRISTIE and ROGERS impute it; and from that circumstance, as well as from the effects of medicines, thinks it a disease of increased vascular action; in which opinion Mr. HAMILTON agrees with him.

8. *Nature of the disease.*—It is evident that the nature of this disease can be inferred only from what is known of its exciting causes, and the ap-

pearances presented after death. Of the former we have imperfect, loose, and conflicting information: of the latter no precise and minute account. It is difficult to explain the early occurrence of the paralytic symptoms. The spinal chord, brain, and nerves supplying the lower extremities, have not been sufficiently investigated to warrant a positive opinion as to the particular state of the parts, to which these symptoms may be referred. The palsy, however, may depend upon congestion of the veins and effusion of fluid within the spinal canal.* The dyspnoea is evidently owing to congestion of the lungs, and oedema of their structure; and the feeble and irregular action of the heart may be imputed to the weakened vital energy and structure of the organ, in connection with effusion of serum in some cases into the pericardium. The effusion of fluid within the serous cavities may, like other effusions, depend upon very different states of the vessels and serous membranes. By Mr. MARSHALL and Mr. HAMILTON it has been viewed as the result of inflammatory action. But where there is merely an effusion of a limpid serum, without either albuminous flocculi or adhesions, there evidently can exist no actual inflammation. Viewing the antecedent symptoms in relation to the post mortem appearances, as far as both have been described, it may be inferred that the disease is more dependent upon active congestion of the lungs, liver, and spinal chord, than upon any of the usual states of inflammatory action; and that this congestion is intimately connected with weakened power of the nervous and circulating systems; manifested chiefly in the heart and extreme capillaries of the cellular and serous structures, with imperfect function of the liver and lungs, and with effusion of serum to a greater or less extent into the shut cavities and cellular structures of the body; giving rise to a nearly universal acute dropsy, and complicated with more or less of paralysis of the lower extremities.

9. IV. TREATMENT.—According to this view of the disease, the discordant accounts given of the success of treatment will be readily accounted for. When the disease prevailed very generally in the Carnatic, during 1782 and 1783, Mr. DICK, who appears to have treated a very great number of cases, found most advantage, during the former of these two seasons, from a pill, containing a quarter of a grain of extract of elaterium combined with extract of gentian, given every hour, until copious watery evacuations were procured; and this plan was repeated every third or fourth day, till a cure was accomplished. In the following season this treatment was not so successful. He found most advantage from large doses of spirit of nitre, antimonial wine, frictions with warm camphorated oil, aperient medicines, and wine to support the strength. Bleeding and mercury were tried without benefit. Dr. CHRISTIE recommended mercury, to excite ptyalism, combined with squills; cordial liquors, consisting chiefly of gin punch; stimulating pediluvia, with warm liniments; and when the patient was convalescent, tonics, composed of bark, wine, and porter. In more urgent cases, he prescribed blisters to the chest, and brandy,

* Since this was written, Mr. MALCOLMSON'S work on the disease has appeared, and proved the correctness of the above remark.

æther, and laudanum, to relieve the vomiting, dyspnoea, and spasms. He found digitalis of no service. MR. HAMILTON's first cases terminated fatally under the plan recommended by Dr. CHRISTIE; and Mr. COLQUHOUN trusted to mercury, but found that many of the patients who died in hospital of the disease were in a state of salivation from this medicine.

10. This want of success led later writers on the disease to have recourse to other means. Dr. HUNTER had tried blood-letting in one case, without any apparent effect either one way or another. Dr. ROGERS stated, in his thesis on the disease, that blood-letting hastened the fatal termination: but, according to Mr. HAMILTON, he has since prescribed it successfully. Mr. MARSHALL appears to have been the first to employ blood-letting in a decided and successful manner in the treatment of beriberi; and the same practice was adopted by Dr. PATERSON (MARSHALL, *on Ceylon*, &c. p. 161.), and by Mr. HAMILTON. The bleeding was large, and repeated; and followed with the internal and external use of mercury, laudanum, and the vapour bath. To these were added purgatives of calomel and camboage.

11. The practice of Mr. RIDLEY, who experienced, himself, two very severe attacks; and who, excepting only Mr. DICK, has had the most extensive experience as respects this disease, having treated almost a hundred cases in one year (1814); recommends a nearly similar treatment to that advised by Mr. DICK. In the early stage, he directs purgatives of calomel, jalap, and crystals of tartar; the lower extremities to be well bathed, afterwards rubbed with camphor and oil of turpentine, or with the mercurial liniment, and then rolled in flannel bandages. He subsequently prescribes a pill, composed of one or two grains of calomel and two or three of powdered squills, every third hour; and a solution of crystals of tartar, as common drink, or made into punch with geneva or arrack. In the more advanced stages, he advises blisters to the back of the neck, or to the seat of pain and tightness; the warm-bath; frequent fomentations of the legs and abdomen, followed by frictions with mercurial ointment, camphor, and oil of turpentine; and clysters with æther, and purgatives. When the dyspnoea, spasms, and vomiting are urgent, he states, that he has given large doses of opium, æther, and brandy, with stimulating diuretics. When they could be retained on the stomach, small and repeated doses of camboage were also exhibited.

12. From the above statements, as well as from the varying character of the disease in Europeans and natives, in different seasons, as observed by Mr. DICK, and Mr. MALCOLMSON, and in various localities,—judging also from the nature and combination of the remote causes, and from the *post mortem* appearances,—I should infer, that a depletory treatment may sometimes be required amongst Europeans; and that the means of cure should be modified according to the characters of the malady and the state of the vital energies; that, on some occasions, general blood-letting—in others, cupping in the course of the spine; blisters; free purging with calomel, camboage, jalap, elaterium, &c.; antispasmodics, consisting of opium, æthers, brandy in some cases, camphor, &c., diuretics, such as squills, cream of tartar, juniper, terbiathinate preparations, &c.; the vapour bath,

or fomentations, followed by frictions with stimulating liniments, mercurial or camphorated liniments, with oil of turpentine, camphorated oils, along the spine and lower extremities; expectorants, consisting of ammoniacum, ipecacuanha, camphor, &c.; constitute the chief means that are likely to remove the internal congestions, to reduce the circulating fluid to a nearer equality with the vital power, to restrain effusion, and to restore the various secretions and excretions of the body. After these means have been judiciously administered according to the peculiarities of the case, or when circumstances seem to require them earlier in the treatment, stimulating and restorative medicines may either be conjoined with the above, or be exhibited alone on such occasions as may require them.

BLOOD. SYN. *Aīua*, Gr. *Sanguis*. Lat. *Sang*, Fr. *Das Blut*, *Gebult*, Ger. *Sanguie*, Ital.

CLASSIF. GENERAL PATHOLOGY—*Ætiology*, *Semeiology*.—GENERAL THERAPEUTICS.

I. STATES OF THE BLOOD IN HEALTH.—1. *A. Of the states of the chyle*. In order to acquire accurate ideas respecting the blood in disease, it is necessary to be acquainted with the varying conditions and appearances of the chyle, according to the food, from which it is chiefly elaborated. To these, however, I can only briefly refer. This fluid, when removed from the thoracic duct, is usually of an opaque white or opalescent appearance, and separates into a serous portion, and more or less firm clot. The former resembles the serum of the blood, the latter consists chiefly of fibrine. If the animal have been fed with fat animal food, the chyle at the time of coagulation assumes a rose colour, and, in addition to the separation of the clot, which falls to the bottom of the vessel, a thin liquid oily layer forms on the surface of the serum. In animals fed on vegetable food, the chyle is generally opaline and nearly transparent, and separates into a serous fluid and a small fibrinous clot only. According to MM. PREVOST and DUMAS the chyle contains globules, similar to those contained in the blood, but of a smaller size. The fibrinous conglutium seems to be formed from their aggregation. The serum of the chyle also contains albumen, and the saline ingredients found in the serum of the blood.

2. *B. The globules of the blood*, particularly in respect of their relation to the other constituents of this fluid, and the changes they experience when removed from the blood-vessels, excite the utmost interest in the mind of the pathologist. It is evident that they are suspended in the serum by means of the vital influence which the blood derives from the vessels and organs in which it circulates. According to the microscopic researches of Sir E. HOME, Mr. BAUER, and of MM. PREVOST and DUMAS, they consist of a central colourless spheroid; and of a species of membranous sac of a red colour, surrounding this spheroid, from which it readily separates after death. The central bodies are transparent and spherical in the mammalia; and, when deprived of

their coloured envelopes, are generally disposed to assume ranges or fibrous meshes. The coloured portion appears to be a kind of jelly, easily divisible; but insoluble in water, from which it may be separated by repose. It is likewise transparent; but much less so than the central corpuscle; and the fragments arising from its division are not susceptible of regular aggregation.

3. *C. State of the blood in the vessels.*—According to the observations of KOLK, THEVRANUS, and others, the globules of the blood possess a rotary motion during life, independently of the motion arising from the impulse of the heart; and this motion continues till coagulation takes place. More recently, this subject has been investigated by Professor SCHULTZ, of Berlin, who has confirmed the fact respecting the intestine motion of the globules, by virtue of which they move on by themselves, surrounded by envelopes of colouring matter, and keeping at a distance from one another. This force, with which the globules of the blood are endowed whilst circulating in the vessels, I have, in my physiological notes, imputed to the influence exerted by the ganglial nerves on the interior of the vessels, which they every where so abundantly supply, as stated in the article on the pathology of the ARTERIES. But, besides this force of mutual repulsion, to which the fluidity of the blood is evidently owing, under the vital influence exerted by the organic nerves on the vessels, there is evidently another force also in action, by which the globules are attracted by the tissues, when they are brought more intimately in contact with them during their circulation in the minute vessels. Whilst, then, the former force keeps the globules in a state of constant motion and repulsion, and is exerted in the stream of the circulation, the latter tends to bring the globules to a state of repose, and is exerted in the organic structures themselves, at the point of contact of the solids and the globules. This latter force, which was first very minutely examined by Professor SCHULTZ, and briefly stated by M. ANDRAL, in his *Pathological Anatomy*, without acknowledgment, may be compared to a vortex whence globules constantly pass from the arterial or terminal capillaries, and are lost in the different tissues. So that, although the vital endowment of the blood is manifested by its fluidity in the vessels, it assumes an opposite manifestation in the capillaries, where this fluid is brought within the sphere of the vitality of the different structures; each one attracting from it those constituents of which itself is formed, and which are always present in healthy blood.

4. Thus we see organisation commencing in the chyle, advancing further in the blood, and reaching its acme in the vital attraction of the constituents of the tissues from the blood circulating in the capillaries which supply them. At this part of the circle, where the arterial capillaries, with the fluid circulating through them, become, as it were, confounded with the tissues in which they are distributed, there appears, according to Professor SCHULTZ, to be not only a constant attraction of particles by the tissues from the blood, but also an equal extrication of other particles from them into the blood received by the radicles of the veins. Thus it appears, that as the proximate constituents of the different tissues exist in the blood, as was first shown by Dr.

PROUT, and subsequently insisted on by MAJENDIE and ANDRAL; and as these become identified for a time with them, are afterwards detached, and flow back into the current of the circulation; the intimate connection and mutual dependence of the blood and the different solids, both in health and disease, ought not to be overlooked. But it is at the same time manifest that these constituents are kept in solution during circulation, and attracted during nutrition, by the vital influence; that the various parts into which the blood separates on removal from the vessels are only indications of its condition when circulating through the frame; that no such separation occurs in the healthy body, and never, excepting very partially, in disease; that this change proceeds from the loss of vitality sustained by the blood when removed from the frame, and that the phenomena connected with it have an intimate relation to the vital endowment of this fluid, derived from the vessels and the nerves supplying them.

5. *D. Coagulation of the blood.*—This process is modified by numerous circumstances, and by various diseases. Generally, however, the blood soon separates into two portions — the serum, and the coagulum or clot; and in this separation the red globules are principally concerned; it being chiefly the result of the loss of the vital motion which these globules possess in the vessels, and of the attraction existing between the colouring envelopes and central bodies. As the vital attraction, which keeps the red substance fixed around the whitish corpuscles, ceases soon after the removal of the blood from the vein, these bodies can then obey the force which tends to unite them, and they then form a network, in whose meshes the liberated red particles are entangled, and thus produce the phenomena of coagulation. If the coagulum be exposed to a stream of water, the colouring matter is washed away, while the aggregates formed by the colourless corpuscles remain in the form of filaments, in which may be recognised an analogous structure to muscular fibre, and constitute the fibrine of the blood.

6. It seems extremely probable, that the colourless globules observed in the chyle form the central corpuscles, and, when they have acquired their coloured envelopes in the progress of sanguification, constitute the red globules. And it appears equally reasonable to infer, that both the suspension of the globules in the serum, and the attraction between their coloured envelopes and colourless corpuscles, are entirely vital, inasmuch as both phenomena cease soon after the blood is removed from its source of vital endowment: and that vital manifestations become first apparent in the chyle, and still more so in the blood; coagulation being the result of the loss of this endowment, and taking place with a celerity in proportion to the rapidity of its departure. In cases where the vital energy, or that manifestation of it exerted by the organic nerves on the vascular system, is unexhausted, or is in a state of healthy excitement, coagulation is perfect and somewhat slow; but where it is depressed or exhausted, this process is quicker, but much less complete. Besides these, it presents various other phenomena, which are intimately connected with the nature of morbid actions, and which I shall notice immediately.

7. *E. Chemical relations of the blood in health.*—The analysis of the blood given by M. LE CANU, who obtained the prize given by the Académie Royale de Médecine of Paris, is extremely minute; and, as respects the principal ingredients, agrees very closely with the results stated by BERZELIUS and MARCET. The oily matter first detected in the blood by DR. TRAIL, and subsequently found by DIS. CHRISTISON and BABINGTON, has likewise been recognised by him as constantly present in the serum. The results of the analysis of the serum by LE CANU, BERZELIUS, and MARCET, are as follow:—

	LE CANU.		BERZ.	MAR.
	1st Anal.	2d Anal.		
Water	906.00	901.00	905	900.00
Albumen	78.00	81.20	80	86.80
Animal matter sol. in water and alco.	1.69	2.05	—	—
* Combined with soda	2.10	2.55	—	—
Crystallisable fatty matter	1.20	2.10	—	—
Oily matter	1.00	1.30	—	—
* Muco-extract. mat.	—	—	—	4.00
* Extractive mat. sol. in alcohol. and acetate of soda	—	—	4	—
Hydrochlorate of soda and potash	6.00	5.32	6	6.60
Sub-carb. and phosph. of soda and sulph. potasse	2.10	2.00	3	2.00
Phosph. of lime, mag., and iron, with sub-carb. of lime and mag.	0.91	0.87	1	0.60
Loss	1.00	1.61	—	—
	1000.00	1000.00	1000	1000.00

8. *The blood, according to M. LE CANU, consists of the following constituents:—*

Water	780.145	786.590
Fibrine	2.100	3.565
Albumen	65.090	69.415
Colouring matter	133.000	119.626
Crystallisable fatty matter	2.430	4.300
Oily matter	1.310	2.270
Extractive mat. soluble in alcohol and water	1.790	1.920
Albumen combined with soda	1.265	2.010
Chloruret of sodium and potassium, alkaline phosphate, sulphate, and sub-carbonates	8.370	7.304
Subcarbonate of lime and magnesia, phosphates of lime, magnesia, and iron, peroxide of iron	2.100	1.414
Loss	2.400	2.586
	1000.000	1000.000

According to some chemists the blood also contains carbonic acid (VOGEL and others); a yellow colouring matter, resembling that of the bile and the urine (CHEVREUL, LASSAIGNE, &c.); and a substance analogous to urea (PREVOST, DUMAS, VAUQUELIN, and SEGALAS). VAUQUELIN and CHEVREUL consider the fatty matter to be similar to that of the brain and nerves.

9. *a.* The quantity of water in the blood of a healthy person varies, according to M. LE CANU, in 1000 parts, from 853.135, the maximum, to 778.625, the minimum. He found the medium quantity in males to be 791.944, and in females 821.764. The quantity also appears to vary with the temperament; as the lymphatic temperament in the male furnished 830.566, in the female 803.716; and the sanguineous in the male 786.584, in the female 793.007.

10. *b.* The albumen contained in 1000 parts of

blood varies from 78.270, the maximum, to 57.890, the minimum. It is nearly the same in the male as in the female, being only about one part more in the former. The difference in the quantity appears to have no relation to the temperament, nor to the age of the subject, from twenty to sixty years.

11. *c.* The quantity of fibrine contained in the coagulium varies extremely. According to BERZELIUS it is only .75 for 1000 of the blood. M. LASSAIGNE states, that the fibrine of the blood of a young vigorous man is only $\frac{17}{10000}$ of its weight. In the researches of M. LE CANU, who has investigated the subject more closely than his predecessors, the quantity of dry fibrine contained in 1000 parts of blood varies from 1.360 to 7.236—the medium of twenty-two experiments being 4.298. It appeared to be greatest in the young or middle-aged of the sanguine temperament, and in the inflammatory state; and least in the lymphatic constitution, the aged, and those suffering under congestion or hæmorrhage.

12. *d.* The proportion of globules varies much more remarkably in the blood of a healthy person, than that of the albumen; the maximum being 148.450, the minimum 68.349, and the medium 108.399, in 1000 parts of blood. The medium quantity in males was 132.150, and in females 99.169. The periods of life intervening between twenty and sixty years had no influence on its quantity, but it was found to vary with the temperament. The medium quantity in the lymphatic temperament was 117.300 among females, and 116.667 among males; and in the sanguineous temperament, 126.174 in females, and 136.497 in males; giving 19.830 more globules to the sanguine temperament in 1000 parts of blood. M. LE CANU found the globules of blood greatly diminished in females subject to a copious flow of the menses. The quantity of globules is also, relatively to the other constituents of the blood, greatly diminished by blood letting, whilst the albumen is not sensibly affected. Thus, a first bleeding furnished in 1000 parts of blood 792.897 of water, 70.210 of albumen, 9.163 soluble salts and animal extractive matters, and 127.73 of globules; but a third bleeding a few days afterwards in the same patient (a female), gave 834.053 of water, 71.111 of albumen, 7.329 of soluble salts and extractive matters, and 87.510 of globules.

11. EXUBERANCE OF BLOOD, *Plethora* (πληθώρα, repletion). SYN. *Polyæmia* (Auct. Var.). *Hyperæmia*; *pléthore*, Fr. *Die Vollblütigkeit*, Germ. *Pletura*, Ital. *Excessive Fulness of Blood*.

CLASSIF. PATHOLOGY.—*Ætiology*. IV. CLASS, II. ORDER (*Author*, see *Classif.* in *Pre-face*).

* Probably the same constituents, differently named, and more minutely examined, by M. LE CANU.

13. DEFIN. *Greater fulness of the vascular system than is compatible with the continuance of health; or repletion of this system.*

14. The importance of attending to the varying states of the circulating system, in respect of both *exuberance* and *deficiency* of the fluid contained in it, has been acknowledged since the time of GALEN. After the doctrine of nervous influence had superseded the humoral pathology, the state of the blood in disease experienced a more general neglect, than the part actually performed by this fluid in the causation and perpetuation of morbid actions ought to have procured for it. Yet have there always been a succession of able observers and writers, who have never lost sight of the influence of the quantity as well as quality of the blood in producing, as well as in modifying, disease; and more recently the subject has deservedly received an increased and an increasing attention. *Plethora* is the opposite of *anæmia*: both may be, to a certain extent, compatible with health; but both predispose more or less to disorder, and, beyond certain limits, constitute distinct and opposite states of disease.

15. I. GENERAL PLETHORA. — A. *States of.* — GALEN, BAILLOU, FERNEL, RIVIÈRE, and others, considered *plethora* to be of two kinds; to which subsequent writers added two more. As these distinctions are still, in several respects, founded in truth, notwithstanding the neglect into which they had long fallen, I will here briefly notice them. 1st, True or absolute *plethora* — *plethora ad usum*; 2d, Apparent, or false *plethora* — *plethora ad volumen*; 3d, *Plethora* relative to space — *plethora ad spatium*; 4th, *Plethora* in relation to vital power — *plethora ad vires*. It will be observed that the first and second of these, the species recognised by the earliest writers, are still upon the whole the most important. In the *first*, the blood is permanently increased beyond the wants of the system. In the *second*, *plethora* is merely a passing occurrence, arising from temporary causes, as the general turgescence occasioned by sudden or high ranges of temperature, &c. In the *third*, the blood may not be increased, but its relative quantity may be too great, as is observed after amputations of one or two limbs. In the *fourth*, the quantity may not be too great, if this fluid were actuated by a healthy state of the vital energy: but it may be excessive in respect of the influence by which it is circulated in all parts of the body. Now, those distinctions are actually founded in nature; and although they may all be resolved into one pathological proposition, viz. greater repletion of the vascular system than the wants and conditions of the economy require, still they must have become matters of experience to every one whose range of observation has been such as entitle his opinions to respect. I shall merely remark upon such of them as admit of dispute.

16. False *plethora* is very generally observed to occur in persons suddenly exposed to elevations of temperature, and depends more upon the effect of heat in exciting the vital turgescence of the capillary vessels, whereby a craving for fluid is created, and a larger quantity is absorbed, than upon the expansion of the fluids themselves, owing to the increase of temperature. A state of false *plethora* is very frequently occasioned, — and is often productive of more serious consequences

than have generally been imputed to it, — by *ingurgitation* and increased temperature conjoined; and it should not be overlooked, that these combined influences not infrequently affect those who are already permanently *plethoric*. This will be more forcibly and truly shown by what must have fallen under the observation of many. A red faced, full veined, and robust looking person, of from forty to sixty, sits down to dinner with a good appetite. He eats three times as much as his body requires, and he excites the stomach to digest it by drinking stimulating fluids to six times the quantity that is necessary. All this, moreover, is done in a close and overheated apartment. The vital turgescence and expansibility of the capillaries and veins are excited to the utmost; the whole surface is full and plump, and the extremities even swollen. Now, a person thus circumstanced, particularly from four to eight or more hours after such *ingurgitation*, actually has the quantity of his circulating fluids increased from one sixth to one third, at a moderate calculation; but the increase is generally soon diminished by the pulmonary exhalation; the urinary, the perspiratory, and intestinal secretions, which are all greatly augmented, and are thus the safety valves of the circulation. But how often, notwithstanding, do we observe the vessels at last yield before the mass which distends or overloads them, and apoplexy, and various other hæmorrhages, and congestions, result; particularly when any one of these safety valves are obstructed or tardy in their action — when the nervous or vital influence is either depressed or much exhausted by the previous excitement, and the vessels are irritated, or their actions otherwise changed by the state of their contents.

17. That *plethora* is a not infrequent result of amputations cannot be disputed, although the privation of sufficient exercise, which is thereby occasioned, will partly account for the occurrence; at the same time we generally observe that the same quantity of food is taken, and the same quantity of blood is prepared for the body, when deprived of one fourth part of the structures requiring support, as was provided for its nourishment when it was in a state of integrity.

18. That *plethora* may exist in conjunction with deficient vital or nervous power, and that, although the quantity of blood in the system may not exceed that of health, and yet be too great for this power to control, cannot be doubted. We are constantly observing such pathological conditions, both at the commencement and in the progress of disease, and frequently remark their influence in its advanced states and terminations. (See article CONGESTION.)

19. B. *The causes of plethora* are so manifest as scarcely to require enumeration. They may operate either singly or in conjunction. They consist, 1st, Of the introduction into the vascular system of a greater quantity of the nutritious elements than is necessary to the support of the organisation: and, 2d, Of the retention in the blood of those parts which are usually removed by the secreting and excreting organs. It must be evident that the former is owing to excess of nourishment and stimulating fluids, whilst the latter proceeds most commonly from insufficient exercise, suppressed natural secretions and excretions, or accustomed morbid discharges. How

remarkably the habits, indulgences, luxuries, and refinement of modern life contribute to these, is sufficiently apparent. At the same time it should not be overlooked that there are certain constitutions, and particularly those of a lax fibre, more disposed to plethora than others, even independently of temperament; that this disposition is often hereditary, and that it is frequently so strong, notwithstanding precautions to overcome it, as to constitute a distinct diathesis. Plethora, particularly in conjunction with a rich state of the blood, is generally most remarkable in those who live highly, drink much, and are very often in the open air, without taking active exercise.

20. There are also certain epochs of life at which it is most apt to occur, particularly when the energies of life are beginning to wane, and when the balance between sanguification and secretion preponderates in favour of the former (see article *Aoe*). Plethora is also more frequent in females than in males, owing to their more sedentary occupations, and to the wants of the female economy, particularly during the period of utero-gestation, and subsequently to the cessation of the menses. It is justly remarked by various writers, that the plethora of early life is generally arterial and capillary: that of advanced age altogether venous.

21. Plethora has been too generally considered as always existing in fat persons, and as occurring at least in them most commonly. But obesity is no sure criterion of plethora; it may even coexist with a deficiency of blood. I have known the supposition, that obesity indicated at least a sufficiency of this fluid, lead to dangerous results. Indeed, the opinion entertained by several of the older writers, that fat persons do not bear depletion, is quite as well founded as its opposite. There are other circumstances besides this which must be taken into consideration, when we estimate either the simple existence of plethora or its extent. This state of the vascular system is sometimes associated with leanness; but when this is the case, the pulse is also full and strong, and the veins very large, full, and rapidly filled upon being emptied by friction. It is more generally observed in persons passing middle age, who, with a ruddy, flesh-like, or lively surface, are beginning to assume greater fulness of the frame without loss of firmness, and in whom the pulse is full and the veins well marked.

22. *C. Symptoms.* — Plethora, in its slightest grades, is generally productive of little inconvenience. There are usually observed merely a greater disposition to sleep than in health; less quickness and aptitude to mental or corporeal exertion: and a more marked disposition to suffer from and to be affected by the more energetic causes of disease. In an advanced degree it occasions lassitude, indolence, vertigo, or weight or pain of the head; heavy, snoring, dreamy, and often unrefreshing sleep; turgescence of the countenance; suffusion of the eyes; fulness of the veins, and of the pulse; occasionally palpitations of the heart, and slight amaurosis. Such are the usual signs of plethora, short of actual disease, at least of such as may alarm the patient. When it proceeds further, it assumes either the features of inflammatory fever, with excess of action in some organ or part, or passes into general visceral congestion, according to the states of vital action

and power. It may moreover occasion, or terminate in, hæmorrhage, visceral inflammations, congestions, and obstructions, active dropsy, morbidly increased secretions, convulsions, spasmodic diseases, morbid states of the vessels, &c.

23. ii. *LOCAL PLETHORA.* — The vessels of an organ or part may be loaded with blood, and yet the state of their vital action may be neither generally or locally exalted to the pitch of active determination, nor reduced so low as that of passive congestion. There are, perhaps, few such cases that are entirely independent of some degree of excitement, arising either from the condition of the nerves of the organ, or from an irritating cause of some description influencing the state of the capillaries. The best exemplifications of this state are the plethoric states of the ovaria and uterus previous to the menstrual discharge; of the generative organs during the venereal orgasm; of secreting glands and parts when their functions are unusually active; of the brain during the exciting passions and emotions (see *Local Determinations of Blood*), and various internal viscera, particularly the spleen, during the cold stage of an ague, &c. These last, however, more nearly approach to congestion than to simple local plethora. It should not be overlooked, that whatever excites the nerves and irritates the tissues of a part, will occasion turgescence of the capillaries, increased flux of blood through the arteries supplying them, and a quicker return of this fluid through the veins. If the part thus excited perform secreting functions, these will be augmented; and thus increased flux and local plethora will both exist, and constitute local determination of blood,—a state which will be considered hereafter. But still this is not inflammation; for as soon as the cause of excitement ceases, this state disappears, without terminating in any of the ways in which inflammatory action terminates, and without having assumed any part of the formative process which in some state or other follows upon inflammation occurring in a previously sound frame. It cannot, however, be denied, that although local plethora does not constitute either inflammation or passive congestion, it will often favour the production, not only of these, but also of hæmorrhages, convulsions, &c. according to its seat and extent, the state of vital power, the nature of the exciting causes, and other contingent circumstances. It is evident that local plethora may occur either with or without general plethora. It may even coexist with insufficiency of blood (§ 34.).

24. iii. *THE TREATMENT* of general and local plethora consists almost entirely of avoiding its causes. Simple plethora does not require, and is seldom permanently benefited by, vascular depletion alone; indeed, it is more generally increased after a time by this practice, unless more efficient measures be also employed. Abstinence, and a free state of the secretions and excretions; active and regular exercise; abridging the period of repose; early rising; a moderate use of diluents, and abstaining entirely from malt and spirituous liquors; cooling and acidulous beverages, when thirst requires to be quenched; are the chief means both of prevention and cure.

III. LOCAL DETERMINATION OF BLOOD.

SYN. *Afflux of Blood; increased Momentum of Blood. Fluxion*, Fr.

CLASSIF. PATHOLOGY. THERAPEUTICS — (*Derivation, Revulsion.*)

25. *The determination of a larger proportion of the circulating fluid to an organ or part, than is usually sent to it in health*, not infrequently takes place independently of inflammation. This state of the local circulation has been, singularly enough, doubted by some writers, and too much insisted on by others, more particularly by Dr. PARRY, who assigned to it a greater importance in pathology than it is entitled to, and overlooked the fact that it is a part only or link in the chain of morbid causation.

26. i. **PATHOLOGICAL DOCTRINE.** — *Determination of blood* is intermediate between inflammation and local plethora. *Inflammation* is an actively morbid state of the capillaries; *congestion* a passive condition of both them and the veins; whilst *determination* is a simply active or excited, but not otherwise diseased, state of both the arterial branches and the capillaries, the veins being unaffected, and readily returning the blood conveyed by the arteries. More or less determination of this fluid accompanies acute and sub-acute inflammations, and hæmorrhages; but it never attends congestion, unless this state pass into either of the former diseases, or be followed by augmented secretion from the congested organ. *Local plethora* (§ 23.) is a lower grade of local determination, or rather an intermediate state of the vascular system between determination of blood and congestion. In other words, (a), *Congestion* of blood is repletion of the veins, attended by depressed vital power — (b) *Local plethora*, increased fulness of the vessels generally, with integrity of vital power — (c) *Local determination*, augmented circulation and vital functions of the vessels — (d) *Inflammation*, an actively morbid state of the vessels, and organic nerves supplying them, tending to change of structure and to disorganisation. As these pathological states are often referred to, and are sometimes improperly confounded, it is therefore necessary to attend to the distinctions now drawn.

27. That determinations of blood actually occur, and may even be excited at pleasure for a short time, are matters of daily observation even in health; and that such changes in the circulation of a part are occasioned by the influence of the nerves, particularly of the organic nerves supplying the vessels, seems an equally well established fact. When these nerves are excited, whether by heat, stimuli, friction, or irritating bodies, the capillaries experience a degree of expansion, — a property with which they are naturally, or rather vitally endowed. The erethism, expansibility, or slight erectility, which is evinced by the capillaries of certain organs in a very remarkable manner, exists more or less throughout

the frame, especially in mucous or cellular parts. When, therefore, this property is influenced by any agent possessed of the power, the diameter of the capillaries running between the arteries and commencement of the veins being increased, an enlarged stream of blood will necessarily pass through them, and a correspondent demand will be made upon the arteries supplying them, owing to the less resistance opposed to the current, and freer circulation in the part thus circumstanced, provided that the return of blood by the veins be not impeded. If the circulation be thus increased as respects the volume of blood passing through the vessels, and continue thus facilitated, the demand thereby made upon the larger vessels and the heart will ultimately tend also to accelerate it, and hence will result augmented volume and quickened circulation — the states constituting determinations of blood.

28. The circulation of an organ or part may long remain in this state, particularly if its vital manifestations do not become exhausted, and if its nervous power continue excited by the agent or cause which first occasioned this condition, or by other influences operating in a similar manner. But if the vital or nervous power become depressed, or otherwise changed, either congestion, or some form of inflammation, will generally ensue, or even hæmorrhage may supervene — a result which is not infrequent when the determination takes place to membranous viscera or parts, and to mucous surfaces. These being, therefore, not unusual terminations of simple determination of blood, means should generally be employed to remedy this state. The agent or cause exciting the vessels should be removed, and other measures directed that may equalise the circulation and diminish its fulness, when the determination is connected with plethora, as it not infrequently is.

29. Determinations of blood to an organ are very frequently occasioned by whatever rouses its natural actions. If the part thus excited perform secreting functions, the increased secretion, in addition to whatever excitement of the vessels may be produced, will of itself determine a greater flow of blood to it. Numerous proofs of this are furnished us by the progress of various diseases, and the appearances presented by others after death; and endeavouring to follow nature, we attempt to remove determination or inflammations in vital organs, by inducing artificially an afflux of blood to parts and surfaces where it cannot be injurious, as to the skin, mucous digestive surface, extremities, &c., with the view of assisting other agents in soliciting or recalling it from the seat of disease. The exercise, also, of organs which possess not secreting functions, will likewise favour an augmented flow of blood to them. Thus, exertion of the mental faculties and the passions determine an afflux of blood to the brain; and of the muscular organs, to the spinal chord, muscles, and heart. It is of importance to be aware that the irregular distribution of the blood, whether of this or of other kinds, may take place either when this fluid is more abundant and richer than natural, or when it is deficient as well as poor; and that the change from the healthy state of the circulation is to be imputed primarily to the state of influence exerted by the organic class of nerves distributed to the vessels, which, thus influenced, control the volume of the blood circulating through

them (§ 27.), as well as modify its states and the rapidity of its circulation. The particular determinations of blood are noticed in their respective articles.

30. ii. THERAPEUTICAL DOCTRINE.—*Derivation*.—*Revulsion*. The doctrine of determination of blood sufficiently indicates the propriety of having recourse to means in the cure of various diseases, calculated to solicit a flow of blood to parts where this may be done safely, and thus to diminish the quantity sent to the seat of disease. This mode of practice was well understood, and very generally employed by the older physicians, upon the well-known pathological principle that, "*ubi irritatio, ibi fluxus*." It must not, however, be overlooked that *irritation* will not always procure afflux of blood; and that it is therefore not altogether identical with *derivation* either in a pathological or a therapeutical point of view. It does not come within my limits to point out the difference; but they are so far alike, that, in order to produce the latter, we frequently have recourse to the former. At the same time we must recollect that *irritation* will sometimes be of service even independently of any afflux of blood that may accompany it, or even although it should fail of producing this effect.

31. It is almost unnecessary to enumerate the means, which we occasionally have recourse to in order to occasion a local determination of blood, and thus derive it from the seat of disease. These consist of numerous agents;—*a*. Such as increase the circulation in the rete mucosum, as rubefacients, sinapisms, external heat, &c.: *b*. Those which, in addition to augmented circulation, procure a discharge from the surface or part to which they are applied, as scalding water, blisters, irritating ointment, &c., purgatives and cathartics, &c.: *c*. Those which, by procuring a flow of the natural secretions, solicit an afflux of blood to the secreting organs, as certain purgatives, diuretics, and diaphoretics: *d*. Those which, evacuate the viscera, increase the discharges from their mucous surface, and augment the secretions in adjoining organs, as emetics, cholagogue purgatives: *e*. Those which influence the circulation in the limbs and extremities, as frictions, the semicupium, various forms of pediluvia, and manuluvia; abstraction of blood from the feet or hands, by venæsection, leeches, or cupping, stimulating or scalding pediluvia, &c.; and *f*. Those which permanently irritate and procure a continued discharge, as deep scarifications, incisions, setons, issues; caustic applications, as the alkalies, the inner bark of mezereon, moxas, &c.

32. All these occasion, in the first place, irritation in the part to which they are applied, and, consequent to this, an afflux of the circulating fluid. Some of them produce the primary, more remarkably than the secondary, effect; and when this is the case, the pain which is felt is often an index of the extent of the former. This is the

case with blisters, rubefacient epithems, sinapisms, and scalding applications; and, therefore, much advantage is obtained from them in various diseases, independently of their secondary operation, particularly when we wish to rouse the torpid or oppressed functions of an adjoining or subjacent organ. When derivation is, however, our principal object, they cannot always be depended upon, particularly in irritable habits, and in the early stages of acute diseases. They ought never to be employed in the stage of excitement in fever, unless this stage be irregular, imperfectly developed, or inefficient; nor in inflammations, until acute action is subdued by depletions, evacuations, and other means,—when only artificial derivation can be expected to have any influence in diminishing the remaining disorder, and lessening the risk of effusion. This caution is especially deserving of attention in respect of blisters,—the cantharides of which, particularly if improperly allowed to remain too long on a place, as they often are in diseases of excitement, being often absorbed into the circulation, thereby increasing the general as well as local vascular action. These applications, also, ought not to be directed to the vicinity of parts suffering from vascular excitement. I have often seen mischief produced by blisters having been directed to the head and throat in acute diseases of the subjacent parts.

33. The means usually employed in order to derive the flux of blood from diseased parts are variously combined, and much discrimination is requisite both in the choice and in the combination of them, appropriately to the state and nature of the diseased action at the time. The scope and limits of this work preclude my entering upon this important branch of the subject; but it has received attention when discussing the treatment of those diseases in which the various means of derivation are required; and the appropriation of those means to the different states of vascular action is there attempted with some degree of precision.

IV. DEFICIENCY OF BLOOD. SYN. *Anæmia* (from the privative *a*, and *αἷμα*, blood). *Bloodlessness*, *Anémie*, Fr. *Der Blutmangel*, Ger. *Dyspepsia Anæmia* (Young). *Marasmus Anæmia* (Good).

CLASSIF. 3. *Class*, Diseases of the Sanguiferous Functions; 4. *Order*, Cachexies (Good). 1. *CLASS*, V. *ORDER* (Author).

34. DEFIN. A deficiency of blood in the whole

body, or in some important organ, not proceeding from natural or artificial hæmorrhage, giving rise to a waxy, bloodless state of the countenance and surface, emaciation, feeble quick pulse, and great languor and debility.

35. Defect of blood, bloodlessness, or anæmia, although not of frequent occurrence, is yet occasionally met with, particularly in its less remarkable, or local forms. In connection with *chlorosis* it is oftener observed. Cases of anæmia have been recorded by REISELIUS, SWENKE, and others; and the disease fully described by BECKER, ALBERT, JANSON, HOFFMANN, DE HAEN, ISENFLAMM, LIEUTAUD, HALLÉ, ANDRAL, and several pathologists, and practical writers of the present day. I shall first offer a few general observations on local anæmia; and afterwards describe more fully general anæmia and its complications. The deficiency of blood, occasioned by natural or artificial losses of it, is considered under a distinct head.

36. i. PATHOLOGY OF ANÆMIA. — 1st, *Local anæmia*. Deficiency of blood in an organ or part is evidently the result of one or more of the following pre-existing lesions: — *a*, Of diminished influence of that portion of the ganglial or organic class of nerves which supplies the blood-vessels of the organ; *b*, Of defective vital expansion of its capillaries, probably owing to the depressed state of the influence exerted on the vessels by the nerves supplying them; *c*, Of mechanical impediments in the way of a sufficient supply of blood; *d*, Of imperfect development, or diminished calibre of the arteries by which blood is conveyed to the organ; *e*, Of disease of the organ or part, or an imperfect exercise of its functions; and, *f*, Of unusual flux of blood to other quarters, causing a proportionate diminution of it in others. It is evident that these states are merely local, and are capable of co-existing with other changes affecting the whole mass of the circulating fluid, as respects both its quantity and its quality; and that various disorders of function, according to the particular state on which the anæmia depends, and the extent to which it may exist, will be the consequence.

37. The organs most subject to this condition of their circulation are, according to M. ANDRAL, the lungs, the brain, the liver, the substance of the heart, the stomach and alimentary canal, and some of the voluntary muscles. To these I would add, the spleen, the ovaria, and the generative organs of the male. In many of these, as in other parts, atrophy is associated with the anæmia; and may be considered, in the majority of cases, as the consequence of it. The *symptoms* of local anæmia are not always manifested during life; but they frequently are, as I shall have occasion to point out, when considering the morbid conditions of those organs most subject to this change. Thus, in the completest of all the states of local anæmia, as when the obliteration of an artery cuts off all supply of blood to the organ, gangrene will result; frequently when anæmia is seated on the brain, a form of convulsion is the consequence, with other symptoms stated in the article on this subject (see BRAIN—*Anæmia of*); and when the ovaria, at the period of puberty is not supplied with the requisite quantity of blood, owing to deficient influence of the ganglial nerves distributed to the organs of generation,

chlorosis, sometimes with more or less of general anæmia, is the constant effect.

38. 2d. *General anæmia*. — The blood circulating through the body may be most remarkably deficient, in respect both of its quantity, and of the relative proportion of red particles. In many cases in which the absolute quantity of blood in the body is diminished, the globules are still more remarkably deficient, they being insufficient to give the blood its usual deep colour. General anæmia presents itself in practice, 1st, as a primary disease; 2d, as a consequence of pre-existing lesions of some one of those organs which are concerned in conveying the nutritious fluids into the blood, or in the processes of sanguification; 3d, associated with other diseases, resulting equally with it from some antecedent affection, the nature of which cannot, perhaps, be readily recognised.

39. *A*. The *primary forms* of anæmia, when closed analysed, seem to proceed, 1st, from deficient nourishment; 2d, from deficient vital power, — from a torpid or depressed state of the influence of the organic class of nerves on the digestive, assimilating, sanguifying, and circulating organs which they supply. — *a*. The influence of deficient supply of nourishment in producing anæmia may be readily imagined, and instances showing it are numerous; I will merely allude to one: — M. GASPARD, whose researches have tended much to advance the state of the pathology of the fluids, has illustrated this part of the subject by observing the remarkable degree of anæmia which existed in a large proportion of the inhabitants of a district devastated by famine, who lived upon grass. A more or common and less expected form of general anæmia is that which arises from the injudicious restriction of diet and regimen, during convalescence from acute diseases, particularly those which have required large depletions. Several instances of this state of disease have come before me, and would, I am confident, have terminated in dropsical effusions (§ 44.) or in death, if a different system had not been adopted.

40. *b*. A torpid state of the organic class of nerves, is one of the most influential, if not the most frequent, antecedent affections to which we can impute this state of the circulating fluid. It is extremely probable that those instances of its occurrence from being shut out from the sun's influence, and the constant respiration of an unwholesome air, arise from the continued privation of salutary stimuli to this important class of nerves, upon which the sanguifying processes depend.

41. The influence of the *sun's rays* in promoting all the vital actions, particularly those of organic life, probably from modifying the electro-motive state of the frame, must be evident to all. The good effects of light and air are shown in the vegetable kingdom, the circulating fluids of which cannot be duly formed without exposure to both. The sun's rays diffuse a genial influence through the frames of the aged, and excite the organic and generative functions of the young. It has been observed that those persons who are entirely excluded from the light of the sun, and breathe the *close air of mines*, are particularly subject to general anæmia. M. CHOMEL has given a very interesting account of the disease which

affected the workmen employed in a coal mine at Auzain. It commenced with colicky pains, meteorismus, blackish green stools, dyspnœa, palpitations, great prostration of strength, followed, in ten or twelve days, by a yellowish or waxy and bloodless appearance of the countenance. The capillary vessels disappeared from the conjunctiva and mucous surface of the mouth; and the pulsation of the arteries could scarcely be felt. The patients complained of palpitations, anxiety, oppression and suffocation on exertion, paroxysms of fever, profuse perspirations, œdema of the countenance, and rapid emaciation. This state continued for six months or a year; and in some cases terminated fatally, with the reappearance of the invading symptoms. Four of these patients were sent to Paris for treatment, and were ordered light nutritious diet, bitter infusions, &c. One of them died; and on dissection, the arteries and veins were found almost void of blood, containing merely a little sanguineous serum; and little or no blood flowed from the parts divided during the inspection. The appearances in this case led Mr. HALLÉ to prescribe iron filings in the dose of a drachm daily, with tonics and opium; and, under this treatment, all the symptoms gradually vanished, the capillary vessels reappearing on the surface.

42. *B.* It is probable that general anæmia will not take place, unless *consecutively* of remarkable torpor of the vital influence, or of some other morbid condition of one or more of the organs which contribute to the formation of blood. Where the digestive powers and the functions of the liver are weakened, anæmia to a slight degree is not infrequent. Its connection with chlorosis is merely that of an associated effect of pre-existing depression of the influence of the system of organic nerves. (See CHLOROSIS.) The lungs have been considered by some authors as the organ which is chiefly concerned in the production of anæmia, and consequently have been viewed by them as the seat of hæmaturia, or at least the place where this process is completed. Without disputing that such is the case to a certain extent, I am disposed to view the liver as being equally, if not more, concerned in this function, — an opinion long since contended for in my *Physiological Notes* (see *Appendix to M. RICHARD'S Elements of Physiology*); and consequently as being in many cases very influential in the production of general anæmia. It is probable, however, that other viscera or parts may also give rise to it. Thus it may be admitted that total obstruction of the thoracic duct will occasion it; and I have repeatedly observed it in children affected with various chronic diseases of the viscera of organic life; being here, as in most cases, one of the results of imperfect digestion and sanguification, as well as of obstruction to the passage of chyle into the blood. One of the most remarkable cases of general anæmia was recorded by Dr. COMBE. In it all the viscera were found nearly bloodless, excepting the spleen; but not diseased in other respects, at least not to the extent of impeding their functions. The thoracic duct and absorbent system were not examined.

43. The *symptoms of anæmia* have been nearly all alluded to in the foregoing remarks. I may, however, enumerate them briefly at this place. They consist of a pale, waxy, or blanched appearance of the countenance and integuments, in

which the cutaneous veins are scarcely seen; and those which appear are pale, apparently empty, do not fill quickly, or scarcely at all, upon pressure made upon them; and, when emptied, fill very slowly. The conjunctiva has lost its red vessels; the lips, tongue, and inside of the mouth are pale; the pulse feeble, small, irregular, and readily made still quicker or fluttering upon mental emotion; the patient is languid and very weak; complains of flatulence, borborigni, and an irregular state of the bowels, with want of appetite, and an occasional nausea; a sense of sinking and syncope, particularly upon assuming the erect posture, followed by palpitations; oppressed, short, hurried, and sometimes gasping respiration; irregular convulsive or spasmodic movements; tremors; œdema of the ankles; and in some cases the more severe symptoms described as following sinking after large depletions (§ 54.). In the more unfavourable cases the patient may be carried off by a fit of syncope upon assuming quickly the erect posture; or by a convulsion; or sink with the symptoms of exhaustion, or with those of effusion on the brain, or in the pleural or pericardial cavities. It most commonly runs into one or more of the complications about to be noticed.

44. 3d, *Complicated anæmia.* — Deficiency of blood, as respects both its diminished *quantity* and its *poor quality*, or the defect of red globules, is often associated with visceral disease, of which it is generally the consequence; but it also may give rise to various affections, both functional and organic. That anæmia should be complicated with certain chronic diseases of the liver, mesenteric glands, and absorbent system, chlorosis, &c. may be expected; but that it should give rise to diarrhœa, and to dropsical effusions in various parts, particularly in the shut cavities and cellular tissue, without any alteration of the solids, may not appear so obvious, although admitting of explanation. M. ANDRAL states, that he has observed anæmia in the bodies of persons who had died dropsical; and in persons who had complained of diarrhœa, profuse perspirations; and very justly considers both the dropsical effusions into the shut cavities and into the cellular tissue, and the exhalation from the digestive mucous surface and skin, as perfectly independent of any local congestion or irritation, and to be analogous to the profuse diarrhœa and perspirations which occur in persons who are brought near to dissolution by long protracted disease. In all such cases, whether attended with effusion into shut cavities or cellular tissue, or with increased exhalation from mucous surfaces, we may consider nearly the same pathological conditions to exist as their principal sources; viz. diminished tone of the exhaling orifices, with lessened vital cohesion of the tissues in which they open; a poor and thin state of the blood, the crasis of which is much lowered; and a more rapid circulation of the remaining fluid.

45. Anæmia, when existing even in a moderate degree, will often give rise to various functional disorders, which are, however, of no constant character, but differing with the temperament, habit of body, &c. The chief of these are hysterical and epileptic convulsions, palpitations, leipthymia or syncope and palpitations alternately, irregular or anomalous convulsions and spasms,

chorea, and various nervous tremors resembling chorea, dyspnoea, sickness or vomiting, œdema, of the ankles, diarrhoea, headach, &c., with weak, small, quick pulse; pale, waxy, or doughy state of the countenance; listlessness, flatulent state of the abdomen, gastralgia, colic pains, very weak digestion, vermination, and irregularity of the fecal and urinal evacuations. It will also be followed by atrophy and softening of several of the internal viscera, and general emaciation.

46. In cases where general anæmia is not excessive, it may be admitted that both inflammation and hæmorrhages may still occur, particularly the latter, from the causes usually producing them; and that they will have a remarkable tendency to terminate unfavourably, owing to the state of the system causing the deficiency of blood, to this defect itself, and to the want of vital resistance, as well as to the incompatibility of most of the means of cure with the state of the constitutional powers and of local action.

47. ii. CAUSES. — Several of the causes of anæmia have been already alluded to (§ 39—42.). There may be others which have not yet been ascertained. I may state, however, briefly and generally, those which have been usually acknowledged. They consist of insufficient and poor food; excessive secretions and evacuations; masturbation practised early in life, and long continued; long exclusion of the body from the direct influence of solar light and rays; protracted confinement in crowded apartments, in the stagnant and impure air of manufactories, especially when affecting children or very young persons; and the constant respiration of a moist, impure, and miasmal atmosphere, from which the sun's rays are shut out. All these exhaust or depress the vital and nervous powers; whilst some also either cut off the necessary supply to the circulating fluid, or waste its richer constituents. To these causes may be added certain malignant organic diseases, as carcinoma, &c., which, in the latter stages, is always attended with more or less of anæmia; impeded development of organs, particularly those belonging to the generative functions, whose perfect evolution is requisite to the salutary excitement of all the organic actions, especially those of digestion and sanguification; and lesions which either impede these latter functions, and interrupt the passage of chyle into the blood, or vitiate these fluids.

48. iii. TREATMENT. — The most rational and the most successful means that can be employed consist of such as are calculated gently to excite and permanently to promote the organic functions. Of these, the most appropriate appear to be the various preparations of iron, bark, sulphate of quinine, camphor, ammonia, small doses of iodine, æther, &c. combined occasionally with opium, hyoseyamus, extract of hops, conium, &c. when the disease is attended with colicky pains. Conjoined with these, the chalybeate mineral waters, cod-liver oil, stimulating frictions of the surface, light and digestible food, gentle exercise in the open air, particularly on horseback, and change of air, will be found of much service. During the employment of tonics, due attention should be paid to the state of the secretions and excretions; and, when the bowels are constipated, the more tonic and less irritating aperients should be resorted to. Of these, perhaps, the best are rhubarb, and

aloes, the aloes and myrrh pill, the compound iron pill, &c.

49. When the anæmic state of the system is attended with hysterical, convulsive, and other nervous affections, a combination of chalybeates and tonics, with antispasmodics, as the preparations of valerian, ammonia, zinc, myrrh, extract of hops, galbanum, æther, strychnine, and various others, is indicated. If we have reason to suspect that the anæmia is a consequence of obstruction or of torpor, combined with an enlargement of some organ or part concerned in the formation of blood, the preparations of iodine, the liquor potassæ alone or combined with tinctics, the subcarbonate of soda, the boracic acid, and bi-borate of soda, are the best medicines with which I am acquainted.

V. MORBID EFFECTS OF LOSS OF BLOOD.

50. This is a subject of greater practical importance than has generally been attached to it; and one which I have had numerous occasions to contemplate, particularly from the years 1816 to 1828, — an epoch during which blood-letting was either more generally adopted, or carried further, than the nature of several diseases, and the constitutions of many patients, warranted. The effects of large depletions have been well illustrated by the experiments of Dr. SEEDS, which have shown, what indeed might have been anticipated from the physical condition of the circulation within the cranium; viz., that we can never hope by depletion alone to materially diminish the quantity of blood in the vessels of the brain. Dr. M. HALL, and the AUTHOR, have also shown that several morbid states may be occasioned by large losses of blood, or by too large a proportion of this fluid circulating in the head, relatively to the rest of the body, as a consequence of large blood-letting; and M. PIRRY has illustrated the same subject by numerous experiments, and has offered many instructive and practical observations on it, particularly in relation to diagnosis.

51. The morbid effects of loss of blood may be advantageously considered in relation, first, to a person previously in health, or not affected by dangerous disease; and, secondly, to persons labouring under different diseases in which loss of blood may occur, either naturally or from injudicious practice. My observations on both these branches of the subject must necessarily be brief, more particularly on the latter, as the topic is not overlooked in the consideration of the treatment of those diseases in which such losses are most likely to be met with.

52. i. MORBID EFFECTS OF LOSS OF BLOOD IN PERSONS NOT PREVIOUSLY AFFECTED WITH SERIOUS DISEASE. — These effects will naturally vary with the suddenness or rapidity of the loss, the extent to which it has proceeded, and the habit of the person, especially as regards vascular plethora, at

the time when it occurred. It is evident that an evacuation which has been rapid will have a more marked and serious effect than the same quantity removed at several times, or in a slower manner; and that, when blood is discharged at intervals, a much larger quantity may be lost without producing the morbid effects often resulting from the sudden loss of a smaller quantity; or, if they occur, they may be of a different kind from those which follow rapid discharges. The subjects, therefore, which chiefly require consideration are, 1st, The immediate effects of large loss of blood; 2d, The more remote consequences; and 3d, The slow and insidious effects supervening on repeated losses, each occurring to a small or moderate extent.

53. *A. Of the immediate effects of large losses of blood.* — *a.* These are vertigo, leipothymia or a sense of sinking, syncope; feeble and slow, or sometimes quick fluttering pulse; slow or apparently suspended respiration for short periods, interrupted by deep sighs; eructations from, and sometimes sickness of, stomach; a cold, pale, and bedewed countenance and general surface; irregular sighing and yawning, generally followed by a return of the pulse and of consciousness; and, if the hæmorrhage is not renewed upon the restoration of the circulation, recovery soon follows. Where, however, the loss of blood is greater, the above symptoms are more marked; the syncope is more profound; the respiration, which is carried on during this state entirely by the diaphragm, is nearly imperceptible, until it suddenly returns at intervals, with deep sighs; sickness and vomiting occur, and restore consciousness for a time, but the patient again relapses into syncope, which is broken in a similar manner; and, if the loss of blood has ceased, a more permanent restoration follows the sighing and sickness, and recovery slowly takes place.

54. When, however, the loss is still greater either absolutely or relatively to the energies of the patient, or if it continue after the above effects supervene, the return of consciousness is often attended with some degree of delirium; a difficult stertorous breathing; dyspnoea; gasping for breath; occasionally retchings, and discharge of the contents of the large bowels; an irregular, intermittent, feeble, or imperceptible pulse; loss of animal heat; great restlessness, violent shuddering, or general tremors, and jactitation, sometimes so violent as to shake the bed upon which the patient lies; a sense of sinking through the floor; convulsions, or tetanic spasms, and contractions; terrible gasping for breath, and death.

55. Such is the common grouping of the morbid effects; but some of them are more marked than others. Thus, when the loss of blood is very large, the patient may suddenly and unexpectedly expire in one of the fits of syncope which occur, or he may sink more gradually, without any appearance of delirium or convulsion, sometimes with the faculties entire to the last. The former may occur after excessive blood-letting or hæmorrhage, when the patient has been incautiously raised up, or when he has not been instantly placed in the recumbent posture when syncope occurred; the latter has taken place unexpectedly when blood-letting has been carried too far, or too often repeated, in the recumbent posture.

56. *b. Convulsions* are often the most marked effect, either of excessive hæmorrhage, or of large and repeated venæsection in the recumbent position; particularly if it be carried to leipothymia or syncope in this position, which ought always to be avoided. This symptom is very common after puerperal hæmorrhagy, or any large losses of blood occurring in females, particularly those of an epileptic or hysterical diathesis, and in children or young subjects.

57. *c. Delirium* is another prominent effect of excessive evacuation of the vascular system; but it usually presents something peculiar. The carotids are often neither full nor strong, the countenance is pale, and the head cool, — symptoms indicating, with the character of the delirium, impaired vital energy of the brain. In some cases the delirium is associated with convulsions, and both may ultimately be followed by coma or lethargy. Delirium more rarely occurs in children or young subjects from excessive loss of blood, than in adult or advanced age; but coma, as will be shown hereafter, is not infrequent in the former, particularly when the loss of blood has occasioned convulsions, which in them usually terminate in coma.

58. *B. Of the more remote effects of large loss of blood.* — When the patient is not carried off by the more immediate effects of excessive loss of blood, reaction generally supervenes, and often becomes excessive. It usually commences with palpitations, and throbbings through the body, but particularly in the carotids and arteries of the head, giving rise to the peculiar noises, of which patients so often complain after large depletions. The pulse now becomes quick, sharp, and soft; and there is sometimes distressing nervous pulsation of the aorta. In the more marked cases of reaction, the patient complains also of pain of the head; intolerance of light and of noise; a sense of tightness or pressure around the head; hurry of mind, and sometimes delirium, particularly in the night; restlessness, agitated sleep, often accompanied with a sense of sinking or impending dissolution, fearful dreams, &c. The arteries throb; and the pulse ranges from 110 to 140, is jerking, sharp, open, and bounding, but readily compressed. The respiration is hurried, panting, and frequent; often attended with sighing, a desire of fresh air, great restlessness; and in females for aromatic perfumes, or the smelling-bottle. The mouth and throat are dry; there is much thirst; and the skin is usually hot, but the extremities, particularly the lower, are generally cold.

59. This state has not infrequently been mistaken for one requiring depletion; and I have met with cases in which the idea of inflammatory action had so taken possession of the mind of the practitioner, as to induce him to employ large or repeated depletion, which had been followed by this state of reaction, for which he was proceeding again to deplete, mistaking the morbid effects of the previous excessive loss of blood for a return of the inflammation. If this state of reaction be not judiciously managed, exhaustion rapidly supervenes; and almost as soon as it occurs death may take place, frequently upon some muscular effort, or upon getting up from the recumbent posture. In some cases, particularly in children and young subjects, the delirium or morbid sensibility of the brain, characterising the reaction,

passes rapidly into a state of lethargy and coma, which on numerous occasions I have seen mistaken for effusion of serum within the cranium, or hydrocephalus, particularly when it has been preceded by convulsions, as is often the case in children. In many such cases, either no effusion is found, or the effusion is to an extent insufficient to account for the comatose symptoms.

60. Under more favourable circumstances the reaction is gradually followed by returning health, or lapses into a state of chronic exhaustion or asthenia, which is variously characterised. In some cases it is attended by somnolency, alternating with slight delirium, &c. : in others, by fits of dyspnoea, palpitations, frequent cough; hurried, laborious breathing; a flatulent, tympanitic state of the abdomen; in several, by pale, emaciated, or discoloured countenance and skin; amaurosis, nervous tremors, or jactitation; delirium, or mania: and in puerperal females by a form of mania which requires to be carefully distinguished, and which is particularly noticed under the article on *Puerperal Mania*. In addition to these functional disorders following reaction after large losses of blood, organic changes may supervene; such as effusion of serum and extravasation of blood upon the brain, effusion into the bronchi and air-cells, dropsical effusions in various parts, and flatulent distention of the stomach and bowels. When recovery takes place, the pulse always continues small and frequent for a long time, owing to the remarkable diminution of the fluid in the vessels.

61. *C. Of the insidious effects produced by small but often repeated losses of blood.*—Loss of blood occurring in this manner produces effects different from those now described. They generally, as may be expected, advance slowly, and often exist either altogether, or a long time, without detection. They are extremely various, according to the age and constitution of the person. They most frequently occasion a pale, leucophlegmatic, and lax appearance of the countenance and surface; a very quick, weak, and irritable pulse; hurried, and oppressed respiration; frequent palpitations, and sense of sinking; borborrygmi, and hysterical symptoms; flatulent distention of the colon, and colicky pains; swellings of the ankles, and dropsical effusions in other parts: in females, difficult and scanty menstruation, chlorosis, deviations of the spinal column, epileptic convulsions, pains in the loins, and various anomalous affections of a painful or spasmodic kind; tremors and irregular action of the muscles; chorea; paralysis; dyspeptic disorders, with irregularity of the bowels; a disposition to syncope; amaurosis; and all the symptoms of anæmia, which indeed is the primary or real state of disease produced, and constitutes the chief change detected upon examination after death; together with serous effusion in some situations, and a pale bloodless state of the viscera, and of the heart itself.

62. ii. OF EXCESSIVE LOSS OF BLOOD IN THE COURSE OF VARIOUS DISEASES.—There are two important considerations which should not be overlooked in practice; viz. that in many diseases, apparently attended with excitement, we shall meet with cases in which the actual quantity of blood in the body is much less than usual; and in various others, blood-letting will often not be

borne, although seemingly indicated, and although the quantity of blood in the frame be not lessened. In illustration of the former of these, I may state that many years ago I had an opportunity of remarking minutely the appearances on dissection of a man of middle age, and somewhat fat, who had complained of an acute and painful disease, obviously functional, for which he had been bled only twice on successive days, and on neither occasion to above thirty ounces; and yet the symptoms of excessive loss of blood appeared, from which he died in twenty-four hours after the second depletion. The most careful examination could detect no organic change, excepting the remarkably bloodless and pale state of all the viscera. Even the brain was less vascular than usual. That in various diseases, unattended by diminution of the circulating fluid, depletion will produce marked symptoms of depression and sinking, owing to the state of the vital power being insufficient to accommodate the vessels, by their tonic or vital contraction, to the reduced bulk of the blood, is well known, and has been fully discussed in the articles on *Adynamic Fevers*, *Erysipelas*, and *Puerperal Fevers*; in which, as well as in puerperal mania, and various other acute diseases, large vascular depletion is often most injurious.

63. *A. Of excessive loss of blood in diseases of excitement.*—The morbid effects of large depletions will necessarily vary with the nature of the disease in which they are employed. When carried too far, in cases of excitement, where the nervous or vital power is not depressed, and the blood itself rich or healthy, reaction generally follows each large depletion, and thus often exacerbates or brings back the disease for which it was employed, and which had been relieved by the primary effects of the evacuation. This is more remarkably the case in acute inflammations of internal viscera, particularly of the brain or its membranes. Thus, every observing practitioner must often have noticed, that a large depletion, when carried to deliquium, will have entirely removed the symptoms of acute inflammation when the patient has recovered consciousness; and that he expresses the utmost relief. But it generally happens that the inordinate depression—the very full syncope that is thought essential to the securing of advantage from the depletion—is followed by an equally excessive degree of vascular reaction, with which all the symptoms of inflammation return; and the general reaction is ascribed entirely, but erroneously, to the return of the inflammation, instead of the latter being imputed to the former, which has rekindled or exasperated it, when beginning to subside. The consequence is, that another very large depletion is again prescribed for its removal; and the patient, recollecting the relief it temporarily afforded him, readily consents. Blood is taken to full syncope—again relief is felt—again reaction returns—and again the local symptoms are reproduced: and thus, large depletion, full syncope, reaction, and the supervention on the original malady of some or all of the phenomena described above as the consequence of excessive loss of blood, are brought before the practitioner, and he is astonished at the obstinacy, course, and termination of the disease; which, under such circumstances, generally ends in dropsical effusion in the cavity in

which the affected organ is lodged; or in convulsions, or in delirium running into coma; or in death either from exhaustion or from one of the foregoing states; or, more fortunately, in partial subsidence of the original malady, and protracted convalescence. Such are the consequences which but too often result—which I have seen on numerous occasions to result, when blood-letting has been looked upon as the only or chief means of cure—the “*sheet anchor*” of treatment, as it has too frequently been called and considered during the last twenty years.

64. *B. Of the mode by which excessive loss of blood in disease may be best avoided.*—*Method of conducting blood-letting.* From the above it will appear obvious, that if blood-letting were better managed, and directed so as to make an impression on the local ailment, but in such a manner as to avoid being so readily followed by the reaction which reproduces the malady for which it was employed, great advantage in practice would result, and much less blood require to be removed even in the most acute cases. *a.* In order to accomplish this, I have long been in the habit—and have inculcated it in my lectures on the practice of medicine, from 1824,—of directing the following mode of practice when large blood-lettings were required in the treatment of visceral inflammation:—The patient should be either in bed, or on a sofa, and in the sitting or semi-recumbent posture, supported by several pillows. The blood is to be abstracted in a full-sized stream, and the quantity should have some relation to the intensity and seat of the disease, and the habit of body and age of the patient, but chiefly to its effects; it should flow until a marked impression is made upon the pulse, and the countenance begins to change. Further depletion must not now be allowed; but the finger should be placed on the orifice of the vein, the pillows removed from behind the patient, the recumbent posture assumed, and the arm secured. Thus a large quantity of blood may be abstracted, when it is required, without producing full syncope, which should always be avoided; and when a large loss of this fluid is either unnecessary, or might be hurtful, the speedy effect produced upon the pulse and countenance by the abstraction of a small quantity will indicate the impropriety of carrying the practice further. In this manner I have often removed about forty ounces of blood, where large depletion was urgently required, before any effect was produced upon the pulse, but always carefully guarding against syncope; and by the subsequent means used to prevent reaction, no further depletion has been required.

65. *b.* In order, however, to obtain this object, a treatment varying with the nature of the disease is required. Repeated doses of the potassio-tartrate of antimony, either given in small quantities at very short intervals, or in large doses, combined with opium; full doses of calomel, antimony, and opium; or of camphor, nitrate of potash, and colchicum; or of ipecacuanha, nitre, and opium, &c., particularly the first of these, exhibited so as to excite nausea, but guarding against retching, as being liable to induce reaction; and the individual antiphlogistic remedies, appropriately directed, and combined according to the circumstances of the case, are the chief means

which I have employed to prevent the return of increased action after blood-letting conducted as now stated. The particular measures which may follow blood-letting are fully explained in the articles on *Inflammation of the different Organs*; but I may now mention, that when opium is given with the view of preventing the recurrence of reaction, it ought to be exhibited in a large dose at once (two or three grains), either with a full dose of James's powder, or any other antimonial, or with two or three of ipecacuanha, conjoined with some one of the other substances above mentioned.

66. It should be kept in recollection, however, that reaction after large depletions is chiefly apt to occur in idiopathic inflammations, and other diseases of excitement, in which the constitutional or vital powers are neither remarkably lowered nor depraved; and when the circulating fluid is not vitiated by the retention of those substances in it which require to be eliminated, nor by the absorption of matters which are foreign to its nature, and injure its purity. Reaction is very apt to follow large losses of blood in acute rheumatism; in inflammations of the membranes of the brain; and, indeed, of all serous or fibro-serous membranes; and by its recurrence to re-animate the local action; so that a person may be bled to that state which has been described as the extreme result of large loss of blood (§ 54.), and yet, trusting to this practice alone, the local disease has either not yielded, or has passed into one or other of the unfavourable terminations it is liable to assume, particularly dropsical effusion. In the course of practice I have frequently seen persons who had experienced attacks either of pleuritis, pneumonia, peritonitis, enteritis, or of some other inflammation, and who had recovered with great difficulty, and after a long convalescence. Upon inquiry, I found that they had always been bled largely, and to syncope,—some of them four, five, or even six times, but scarcely ever less frequently than thrice; and yet, upon a subsequent attack of inflammation in its most acute form, in the same or some other organ, a single depletion, practised as I have recommended above, and followed by the means most likely to prevent the return of reaction afterwards, to subdue the local action, to solicit the flow of blood to other parts, and to equalise its distribution over the body, has been sufficient; or, at most, a single repetition of the venesection has been all that has been required.

67. *c.* When the chest is dull on percussion, the heart congested, the liver large, and the veins distended; or when the circulation is full and strong, the capillaries injected, the lips and mucous surface red, the muscles firm and large, or the respiration oppressed, blood-letting is generally required, and is well borne. It is also necessary even when the pulse is languid, the external venous circulation difficult, and the surfaces pale, if these symptoms be conjoined with those indicating internal congestion. (See CONGESTION.) On the other hand, persons with an open, soft, full pulse, florid countenance, lax muscles, &c., although they may bear moderate loss of blood, yet suffer more from large depletions than those of a pale, dry, thin, but muscular and rigid habit of body.

68. Under no circumstances ought a patient to

be bled whilst his head is nearly on the same level with the trunk; and the utmost care should be taken in having recourse to venesection in cases of dilatation of the cavities of the heart, particularly those of a passive nature. It is seldom necessary in such cases: and if circumstances should arise to require it, the blood should be taken, in the position I have inculcated (§ 64.), from a small orifice and to a small extent. In the majority of cases, the state of the venous circulation, if duly examined, furnishes some information as to the quantity of blood in the system, and therefore sometimes becomes a valuable guide to blood letting in some doubtful cases.

69. When the superficial veins are distended, of a deep or dark colour, and the blood flows quickly, and the veins fill rapidly on applying friction and pressure—indicating that their usual state of fullness does not depend upon interrupted circulation about the right side of the heart, or in any part of their course—we may infer that the system is sufficiently supplied with blood. But if the veins are small or pale, the body not being fat; if they swell slowly upon a ligature being applied above them; or are readily emptied by friction, and very slowly refilled, we must infer the existence of a feeble state of the circulation, and a deficient as well as poor state of the blood: and the inference will be further verified if we find this state associated with a pale sickly appearance of the countenance and integuments; a small, feeble, and quick pulse; and paleness of the lips, conjunctiva, tongue, and gums. (See § 43.)

70. *C. Of loss of blood in relation to diseases of depressed vital power, &c.*—There is a numerous class, or rather classes, of diseases, in which blood-letting, either in small quantity, or carried too far, is especially injurious. All those in which the circulating fluid is poorer and thinner, or less pure, than in health, particularly chronic and malignant diseases presenting more or less of the symptoms of anæmia, and disorders occurring in ill-fed and emaciated subjects; those in which the vital endowment of the blood-vessels, or their tonic contractibility, is partly lost, or manifestly reduced, as various forms of fever, puerperal and other diseases in which hurtful matters are apt to pass or to be absorbed into, or not to be eliminated from, the blood; all those in which the vital cohesion of the soft solids is diminished, and the fibrine of the blood is incapable of cohering in the manner necessary to form a tolerably firm coagulum, are injured by large bleedings, or even by depletion to any extent. In the first of these, it is obvious that blood cannot be spared: in the second, although its loss might not be felt in other respects, the vessels cannot accommodate themselves to the state of their contents when any considerable quantity is abstracted; and in the last, as well as in them all, the vital manifestations of the circulating system, and of the solids generally, of which cohesion is one, is so far injured, that the primary morbid condition from which they all proceed is increased by the operation; and, moreover, a greater disposition to the absorption of morbid matters is imparted to the absorbing function, when such matters are within the sphere of its operation, by the vascular depletion.

71. I may, in conclusion, remark, that all diseases essentially spasmodic, and consisting of

irregular action of muscular parts, or of altered sensibility of nerves, or of morbid exaltation of their peculiar sensibilities, even when affecting internal organs or the heart itself, and when no conclusive evidence of inflammation exists, will either be aggravated by loss of blood—in some cases even to a moderate extent—or be readily followed by the effects which have been described as consequent upon an excessive evacuation of this fluid. But I may further add, that, in many cases where the above reasons for abstaining from large or repeated depletions, or from venesection, strictly apply, local depletions, under due restrictions, may be resorted to with advantage.

72. *iii. TREATMENT OF THE EFFECTS OF LARGE LOSS OF BLOOD.*—This will necessarily vary with the particular effect produced, and the state of the patient, and of the disease in which excessive loss of blood occurred. The more immediate effects of the loss are the first to claim attention; the other morbid conditions which result from it more remotely, will be considered in succession.

73. *A. Treatment of the primary effects of loss of blood.*—The more immediate effects (§ 53.) generally require the recumbent posture, free ventilation, and airy apartments; in the extreme cases, stimulants, sprinkling the face with volatile and fragrant fluids, and even the transfusion of blood. In the worst cases, and particularly when the loss of blood has occurred from the rectum or vagina, the head and shoulders should be placed lower than the pelvis; and care should be taken to ascertain whether or no internal hæmorrhage is going on, as far as this may be accomplished (see *Uterine Hæmorrhage*). In all cases of hæmorrhage, the involuntary discharge of urine and evacuation of the bowels ought to be considered most dangerous symptoms—even more so than the occurrence of convulsions—and the most decided measures should be instantly adopted. Where we have reason to suppose that transfusion will be required, it should not be delayed too long, as the risk from delay is infinitely greater than that from the operation performed by an expert surgeon, and with a proper apparatus. In cases where convulsions or delirium occur, or when these pass into coma or lethargy, it will be necessary to exhibit, internally, stimuli, as æther, spirits of ammonia, and camphor, with a little tincture of hyoseyamus; to sprinkle æther, or lavender water, or eau de Cologne, over the face and head; to apply a blister to the nape of the neck, or on the epigastrium; to support the animal heat in the trunk of the body and extremities; and to administer the lightest and blandest nourishment. Recovery from large loss of blood is usually quick, when the functions of digestion and assimilation have not been greatly injured by it; but when they remain imperfect, or remarkably disordered for some time afterwards, we may dread the formation of visceral disease, and should direct change of air, voyaging, and travelling, with the use of tonic and deobstruent mineral waters, and appropriate internal medicines.

74. *B. Treatment of reaction after large loss of blood.*—Careful reference ought to be had by the inexperienced practitioner to the symptoms indicating this state (§ 58.), so as to distinguish between them and the general excitement consequent upon internal inflammation. This state will require means modified according to the fea-

tures it assumes. But generally the morbid reaction existing in the head, and rendering all the senses remarkably acute, and the system susceptible of impressions, as well as the distressing palpitations of the heart, require the utmost quiet, and small doses of hyoscyamus, or extract of hops, with the preparations of ammonia, and mild nourishment. Where the throbbings or pains in the head are urgent, the surface of the head warm, or delirium exists, cold spirituous lotions, applied over the head, and full doses of hyoscyamus with ammonia, or moderate doses of the acetate or the hydrochlorate of morphia, with weak brandy and water, and warmth applied to the lower extremities, will be required.

75. *C. Treatment of consecutive exhaustion, or sinking.*—Here stimulants are required in larger doses; and should be administered by the mouth, in the form of enema, and externally. It is possible that transfusion would also be of service in this state of the system. If coma be present in this stage, large doses of camphor, æther, and ammonia are required, with the tepid effusion on the head; blisters, or mustard cataplasms to the nape of the neck, or epigastrium, or to the feet. In more chronic cases of exhaustion or sinking, gentle nourishment, in small quantities and often; warm tonics, combined with gentle aperients, in order to remove morbid secretions, and relieve flatulence; nutritious enemata, or injections of gruel or mutton broth; and small quantities of weak brandy and water; are the best means that can be adopted.

76. *D. Treatment of certain effects of depletion in relation to disease.*—*a.* Large loss of blood during diseases of excitement (§ 63.) requires a treatment but little modified from that already recommended. When it has occurred during inflammation, a certain degree of irritative action may still continue, notwithstanding the excessive loss of blood, occasioning dropsical effusion into shut cavities; and, when the disease is seated in the lungs, effusions in the bronchi or air-cells, which the powers of life are insufficient to throw off, or to expel. In such cases external derivatives, and a combination of gentle stimuli, with diuretics, anodynes, and diaphoretics, in order to equalise the circulation, and to lower the irritative action in the part affected, often prove of service. When the primary disease is seated in the head, the tepid or cold effusion, cold lotions to the head; external revulsants applied to the nape of the neck, or to the lower extremities; anodynes, camphor, with hyoscyamus, or with acetate of morphine; and the promotion of the alvine and cutaneous secretions and excretions, constitute the principal measures, together with those already enumerated (§§ 74, 75.).

77. *b.* Loss of blood occurring during diseases of vital depression (§ 70.) requires the most energetic means. The objects very generally are to restore, as far as may be, the vital endowment—the tonic contractility, of the vascular system, and to enable it to act with sufficient energy on the fluid circulating through it; to increase the vital cohesion of the soft solids; and to excite the secreting organs to remove the hurtful ingredients that may have passed into or accumulated in, the remaining fluid, and which tend to vitiate the whole of the structures, and to sink still lower the already depressed powers of life. These ends

can be attained only by exhibiting, in frequent doses, the various tonics and stimuli; particularly those which tend to arrest or to counteract the morbid changes going on in the frame, and to rally the powers of life. Of this kind are the preparations of bark, or quinine, combined with camphor, the æthers, particularly hydrochloric æther, the preparations of serpentaria, spirits of turpentine, wine, opium, and various remedies of the same description, combined according to circumstances, and generally exhibited in small or moderate doses frequently repeated. External stimuli, rubefacient cataplasms and liniments, stimulating and tonic enemata, injections of mulled port wine, with opium and camphor, are often of great benefit. When the secretions require to be carried off, rhubarb and other tonic aperients may be employed. When the disease is attended with *coma*, blisters or sinapisms to the nape of the neck, epigastrium, or the feet, may be employed; and either of the following formula, in the *Appendix*, exhibited (see F. 423. 496. 845. 906.). If low muttering *delirium* be present, the same treatment as is recommended for this state in typhoid fever is required.

VI. ALTERATIONS OF THE BLOOD IN DISEASE.

78. It will be necessary to the accurate estimation of the causes and results of the various changes of the blood in disease, briefly to consider the relation in which the different functions of the body stand to the blood. These functions are of the following kinds: viz. of *sanguification*, *nutrition*, *deuration*, and *secretion*; one organ performing, or contributing to two, or even three, of these offices. We know that digestion, absorption, arterial circulation, and respiration, are necessary to the formation of the blood, and to the nourishment of the tissues, we also know that absorption, nutrition, secretion, and venous circulation, are concerned in rendering the blood impure, by conveying hurtful ingredients into it, or allowing others to accumulate in it, or by destroying the relative proportion of its constituents; and that various organs, particularly those of secretion and respiration, are actively concerned in eliminating such matters as become injurious by excess, or pass into the circulation from the various sources of impurity which surround it. Hence it must be evident, that changes in the solids, and particularly in those viscera which are concerned in the supply and waste of the blood, as well as in its deuration, must be followed by changes in the state of this fluid; unless when one or two organs merely have their functions interrupted, and others performing analogous actions to these disorders assume a vicarious office. It must be evident, therefore, from this, that the doctrines of solidism and humorism are, to a certain extent, both correct; that, although disorder may originate in either, it cannot be long limited to one or the other, but must extend more or less to both, according to the nature of the causes, and the organs or parts where their impression is made. We observe in the course of practice, that certain morbid or poisonous ingesta make but little im-

pression on the system, until they are absorbed into the circulation, and by their presence there disorder various organs or parts; whilst other substances make an immediate impression on the nervous system, and, through its medium, impede the functions of secretion and depuration, and thus the blood itself is rendered impure, and the source whence all the frame is more or less vitiated. Various fevers furnish most satisfactory illustrations of this position.

79. Having already considered changes in the quantity of the blood, alterations in its qualities are next to be viewed. The facts which have been observed, connected with this subject, are few and deficient in precision; and the majority of those who have directed their attention to it, have merely described chemical conditions and combinations presented by this fluid after it had been for some time removed from the body, and had lost whatever vital endowment it may have received from the vessels and tissues in which it circulated, or had undergone important changes incidental to this state; instead of describing at the same time such vital manifestations as it may have presented upon its removal, and the relation of its chemical states to the pathological conditions of the body.

80. As we have seen that organisation commences in the chyle, and that this fluid is the chief source whence the blood itself is formed, the importance of studying the alterations of the blood, in connection with the state of this fluid, is evident; but the difficulty of the investigation generally precludes many from engaging in it. At the same time it must be admitted, that very important changes may take place, not only in the blood, but also in the fluids which supply it, and are secreted from it, without being made manifest to our senses upon the most careful examination. I shall now, *first*, furnish proofs of important changes in the constituents and state of the blood in various diseases; and next consider the causes of such changes, and the results to which they usually lead.

81. *i.* PROOFS OF CHANGE. — *A.* In the proportion of the chief constituents of the blood. *a.* The quantity of albumen varies considerably in disease. It is not sensibly diminished by large or repeated blood-letting, unless the quantity of blood, in relation to the bulk of the body, be much diminished. In many inflammatory diseases, and in a large proportion of cases of active dropsy, the relative proportion of albumen is often very much increased. This has been shown by BLACKALL, TRAIL, GENDRIN, BRIGHT, and several authors. I have always found it remarkably increased in most of the exanthemata, particularly before the eruption has come out. GENDRIN shows that, in inflammatory diseases, the serum of the blood often contains twice as much albumen as in the healthy state. When this is the case, the blood feels remarkably viscid to the touch. In diseases of debility, and when the blood is apparently deficient in quantity, and poor in quality, the albumen is generally very much diminished, being sometimes less than half its usual proportion. M. GENDRIN and M. ANDRAL think that it may also be altered in its nature as well as quantity; and I believe, from appearances which I have observed in the advanced stages of several diseases, that their opinion is correct. In these cases,

the albumen seems either precipitated to the bottom of the serum, or suspended in it like a cloud, giving it a turbid opacity.

82. *b.* The proportion of the watery part of the blood has been shown to vary in health; but it varies still more in disease, and even in different stages of the same malady. This change is not, however, limited to one, or even a few, of the constituents of this fluid; but sometimes is extended to the most of them. Blood-letting, in acute diseases, diminishes the proportion of coagulum; and, if diluents be supplied, increases greatly the proportion of serum, without lessening the quantity of albumen, unless the depletion be carried very far. In several chronic diseases of debility, in the stages of excitement and exhaustion in fevers, and in the last period or decline of the acute exanthemata, the proportion of serum is very considerable, owing to the interruption of the secreting functions; but in acute inflammations, and the early stages of some of the exanthemata, the blood is of a deep colour, and rich in cruor, with an increased proportion of albumen and of fibrine. In the advanced stages of disease, attended with fluid evacuations, the watery part of the blood is diminished. This is remarkably the case in the pestilential cholera, dysentery, and in some forms of dropsy.

83. *c.* The colouring matter of the blood evidently undergoes some alteration during febrile and malignant diseases. It has recently been supposed that such change has an intimate connection with the proportion of the saline constituents of this fluid,—a diminution of these rendering the colouring matter dark coloured, whilst an increase of them has an opposite effect; and certainly various facts seem to confirm the opinion. But this alteration is one merely in relation to colour, which is unquestionably rendered much more deep or black in the last stages of the diseases now alluded to. But besides alteration of colour, there are others which may be termed *dynamic*, inasmuch as they relate to the vital endowment of the globules, or, if not of the globules, of the fluid generally. In the diseases referred to, and after the operation of virulent poisons, the condition of the colouring matter is remarkably changed: it separates readily, and almost before dissolution, from the central corpuscles which it surrounds; and, passing through the exhalant vessels of mucous surfaces, with the serous or watery part of the blood, gives rise to the sanious cruor, and the dissolved blood, which we sometimes observe issuing from these parts shortly before or after death; and probably to the black vomit in yellow fever. In cases of infection by animal poisons or morbid secretions, this separation of the colouring matter, and solution in the serum, take place very early, indeed almost immediately after death; and it is evidently owing to this change of the blood, that the interior surface of the blood-vessels becomes so deeply coloured, without any other appearance of inflammation. Indeed, the evidence adduced by M. TROUSSEAU fully proves this to be the case. (*Archives Gén. de Méd.* t. xiv. p. 321.) This further accounts for the coloration of the interior of arteries in fatal cases of adynamic or malignant fevers,—an appearance first particularly noticed by J. P. FRANK, and subsequently by many others, and by some incorrectly ascribed to inflammation.

84. *d.* The *fibrine* varies greatly in its quantity, and as to the states in which it presents itself in the blood removed from the body. Its condition will be somewhat modified by the manner in which blood-letting is performed; but generally it soon separates from the serum, and, with the red particles, forms the crassamentum or clot, which will vary in its appearances with the degree of nervous energy exerted by the organic nerves on the vascular system, and the quantity of fibrine. *a.* First, the fibrine and red globules may be in much greater proportion relatively to the water and albumen, and still the crassamentum formed therefrom will be very different, according to the state of vascular action and nervous energy at the time when the blood was abstracted. If the vascular action be increased, or in a healthy state, and the vital energy unexhausted, the fibrine will contract into a firm and large coagulum. If the fibrine retain its relatively large proportion, and vascular action be exhausted, it will contract so imperfectly or loosely, as to enclose a large portion of the serum, and to leave but little of this fluid surrounding it. In the former case the coagulum possesses much density: in the latter, extremely little; indeed, sometimes not sufficient to separate it sensibly from the serum. In such cases the blood is *rich*, although otherwise very different in appearance, owing to the state of action and vital power.

85. *β.* In the *second* place, the fibrine may be in small quantity, and yet present a state of firm attraction, forming a small coagulum in the midst of a larger proportion of serum than is usual in health. Or the proportion being still small, the cohesion of the fibrine may be so weak as to form a tolerably large coagulum; whilst, in other cases, it will scarcely separate from the serum, owing either to its diminution, or the weak attraction of its corpuscles. I have met with it in several cases so nearly wanting, and so deficient in attraction in other instances, as not to form any coagulum; the red particles having been, as it were, precipitated to the bottom of the vessel in a dark or blackish sediment, without any cohesion in the form of clot. From this it will be inferred, that the quantity of fibrine cannot be reckoned from the apparent size of the coagulum merely, but from the size in connection with density or degree of cohesion. When the blood is deficient in red globules, and fibrine, it has usually received the appellation of *poor* blood; the degree of cohesion existing between the particles of fibrine in it, as well as in rich blood, being the general index of the degree of nervous power. But there are apparent exceptions to the indications it presents. Thus, in acute rheumatism, after repeated depletions, injudiciously resorted to,—injudiciously, because a frequently injurious, and seldom a beneficial practice—and during the reaction consequent upon repeated blood-letting, the fibrine, although much reduced in quantity, will often still continue to adhere firmly, or even to form, in some cases, a buffy coat, and yet the powers of life are reduced very far beyond what the state of the fibrine would seem to indicate. In these cases, the cohesion of the coagulum, and the formation of the buff, are, as well as in many other circumstances of disease, principally the result of vascular reaction, occasioned by morbid excitement of the nervous influence; and as long as these states exist, this

condition of the coagulum will occur, although depletion be carried to the utmost extent.

86. *γ.* Whilst the blood is still circulating in the body, particularly in the last stages of various chronic diseases, the repulsion existing between its existing globules may be so far destroyed as to admit of the fibrinous corpuscles adhering to each other, in some part of the vascular system, or even in one of the cavities of the heart. The fibrinous concretions thus formed are attributable, 1st, To retarded or obstructed circulation of the blood in the part. VAN SWIETEN and HALLER state that flocculent and fibrinous coagula have formed in the blood of the pulmonary artery during syncope and the cold stage of agues; and they, as well as numerous later observers, have found these productions after exposure to extreme cold, and when death has been preceded by a very languid, obstructed, and irregular state of the circulation. 2d, To effusions of a small portion of coagulable lymph from the inside of a part of the vascular lining, during a state of inflammatory irritation; which lymph may have become the nucleus around which the fibrinous particles may have collected, or the bond of cohesion between them in the first instance: and, 3d, Particularly as respects those fibrinous concretions, in the centres of which purulent or tubercular matter has been found, as in the instances adduced by MM. LEGROUX, MARÉCHAL, and subsequently by others, to the absorption of these matters, or to their passage into the blood from the internal coats of the vessels on which they may have been formed; and from becoming nuclei around which the fibrine has concentered. In some instances, in which these fibrinous masses have been found, little or no connection with the surrounding vessels can be traced. M. ANDRAL supposes that these concretions are possessed of a separate vitality, and that the matter detected in their centres is a product of vessels previously formed in them. This opinion, however, cannot be supported, inasmuch as the matters formed in their centres have no relation to, nor have they been found often surrounded by, blood-vessels; and, when vessels have been detected, the firm attachment of the concretions to the inner surface of the vessels attests the manner of their formation to be identical with that of other productions of a similar kind.

87. *δ.* But the attraction between the particles of fibrine, which is usually observed when the blood is removed from the sphere of vital endowment, in which it participates, instead of being exerted, as now stated, within some part of the vascular system, may be entirely lost, or be very irregular or imperfect. In such cases, the blood either remains altogether fluid; or its fibrine, and some part of its albumen, form grumous particles, or minute fragments, which are either suspended in the serum, or mechanically mixed with it, forming a sanious cruor in the vessels. This latter state is observed sometimes locally, and often generally, immediately after death; as in the veins of the spleen, liver, of the extremities, &c. A thick, dark, and treacle-like state of the venous blood, and a venous appearance of the arterial blood, are not infrequent during life; particularly in pestilential cholera, in asphyxia, hydrophobia, &c.

88. *ε.* The *buffy coat* observed to form the upper part and surface of the coagulum, most frequently, in cases of inflammation, consists of fibrine,

according to DEYEUX and PARMENTIER; of fibrine, and especially concrete albumen, in the opinion of FOURCROY, VAUQUELIN, and THENARD; of fibrine and gelatin, according to ORFILA; of fibrine, containing serum between its fibres, and albumen, or very albuminous serum, according to DOWLER and GENDRIN. BERZELIUS considers that it may contain all the elements of the coagulium. It manifestly is produced by the concretion of the fibrine, which, parting from the colouring matter, forms a whitish yellow, or slightly greenish layer, varying in thickness from a line to one or two inches; and giving rise to the *cupped* appearance of the clot, by the firmness of attraction between its particles. The formation of the buff may be somewhat favoured by the size of the orifice from which the blood has been drawn, the rapidity with which it has flowed, and the form of the vessel in which it has been received; but the buff itself entirely depends upon the state of the fibrine, which, in conjunction with a portion of serum and much albumen, not only chiefly constitutes it, but modifies it in the manner already noticed, according to the state of vital influence and vascular action. (See § 84. and art. INFLAMMATION.)

89. *e.* Respecting changes in the *saline constituents* of the blood, we are provided with but little information, and that by no means of a precise character. So much difference has existed amongst chemists respecting the actual saline ingredients of healthy blood, and their state of combination in this fluid, that a standard has not been furnished for comparative observation. According to Dr. STEVENS, they are very sensibly diminished in the blood of patients affected by the fevers of warm climates; and Dr. O'SHAUGHNESSY has shown that the blood of those suffering from pestilential cholera contains much less saline constituents than in health.

90. *f.* The *electrical condition* of the blood may also be changed by disease. BELLINGERI states the electricity of venous blood to be equivalent to that of antimony; that it is an imperfect conductor of this agent; and that its electricity is diminished in inflammatory diseases. According to ROSSI, the blood presents, in severe fevers, modifications of its electrical states. That electricity, when acting energetically on the frame, affects the blood (probably through the medium of the nerves supplying its vessels) in a most intense manner, is shown by the dissolution and decomposition of this fluid after death from this agent. The evident effect of light upon the blood, in rendering it both more abundant and rich, may be attributed to the electrical states of the solar rays.

91. *g.* The *temperature* of the blood has been observed to vary, during the course of disease, from 86° to 104°. It has been observed as low as the former grade in pestilential cholera, and the cold stage of ague; and as high as the latter in the stage of excitement in fevers, and visceral inflammations. Its temperature is evidently owing to the degree of nervous power in connection with vascular action.

92. *B.* *Changes in the intimate nature of the blood, for which mere difference in the proportion of its constituents cannot account; and which are referrible to the state of vital power.*—Important changes of the blood, which are evidently not referrible merely to alteration of the healthy proportion of its

constituents, although such alteration may be considered as often co-existing with those other inappreciable modifications upon which its morbid effects chiefly depend, occur in the course of various diseases; and, when once induced, occasion not only violent or fatal effects as respects the individual subjects of them, but also similar changes in healthy persons inoculated with this diseased blood. Dr. HOME communicated measles by means of blood taken from persons affected by them. DUHAMEL records a case of a butcher, who, having put in his mouth the knife with which an over-driven ox had been slaughtered, had his tongue and throat swollen a few hours afterwards, and an eruption of blackish pustules over his body. He died in four days. Another person, having wounded himself in the hand with a bone of the same ox, was seized with inflammation of the arm, followed by mortification and death. Two females experienced also gangrenous inflammation from a few drops of the blood of the same animal having fallen upon the hand of one, and on the cheek of the other. Inoculation with, or even the simple contact of, the blood of diseased animals, may produce in men the malignant pustule. Of this numerous proofs have been furnished. MM. DUPUY and LEURET introduced into the cellular tissue and veins of a sound horse, blood taken from a horse affected with malignant carbuncle (*pustule maligne*), and thus produced the disease. The serious effects also observed to follow wounds in dissection, either of recently dead bodies, or those in which decomposition has commenced; the changes which take place in the blood, either primarily or secondarily, in various maladies; the septic influence of certain animal secretions and poisons on the tissues to which they are applied, on the blood, and on the frame generally; are among the most important phenomena of disease. I shall, therefore, proceed to a more minute examination of this department of pathology than it has recently received. That these changes are of a most important nature; that they may arise from various causes, or from spontaneous alterations taking place in the blood while circulating in the vessels of the animal, even whilst those changes are so slight as to escape detection by our senses; and that the blood, when thus changed, will be the cause of disease presenting a malignant character, when applied to or inserted into the tissues of healthy animals, are facts which the preceding, as well as other evidence about to be adduced, fully demonstrate. The chief of these changes, to which I attach the utmost importance, having observed them to exist more or less in a large proportion of cases where blood has been removed, or escaped from a vessel, in malignant or adynamic diseases, or in the last stages of very acute and dangerous maladies, are the following:—

93. *a.* The blood has generally a somewhat salt taste in health, evidently depending chiefly upon the quantity of chloride of sodium contained in it. In various maladies, particularly those which are malignant, and in the advanced stages of fevers, the taste is not so remarkable, particularly when the blood assumes a darker hue than natural. *b.* The peculiar odour of this fluid upon emission from a vein is also very remarkably changed in these maladies. HALLER has adduced numerous instances of this in his great

work; and various authors—and amongst these, VAN SWIETEN, HOFFMANN, SCHWENCKE, HUXHAM, LININGS, &c.—have noticed a remarkable factor of the blood in adynamic fevers and pestilential maladies. I have observed a peculiar odour of the blood in cases of malignant puerperal fever. We are informed by LOUIS DE CASTRO, that the blood of two plague patients infected the air of their apartment with a foetid odour; and ZACUTUS mentions, that three persons were struck dead by the odour exhaled from the blood drawn from the vein of a person infected with plague. MURALT also states that a cadaverous factor emanates from the blood of persons affected with this malady; and BAGLIVI mentions that a nearly similar phenomenon was observed in the blood of patients in the advanced stages of a very fatal epidemic fever. HALLER prognosticated a fatal issue, chiefly from this symptom, in a case to which he refers. ZURINUS, ALPRUNNER, and VATER, allude to cases where physicians were dangerously infected by the factor of the blood, upon its abstraction from the veins of persons in malignant and contagious diseases. BOISSEAU states, that he has been very disagreeably affected by the odour of the blood just abstracted from the veins of persons attacked by severe disease of the chest or abdomen. PRINGLE relates, that an individual was seized with dysentery, after inhaling the odour from the blood of a dysenteric patient, kept for a long time. The blood taken from a vein in the arm of a woman in a malignant fever, was, according to MORTON, so offensive, that the surgeon and assistants fainted in consequence. It may be therefore inferred that both the odour and the taste of the human blood may be very sensibly changed in the advanced progress of various adynamic, infectious, and malignant maladies.

94. c. Softness or firmness of the *coagulum* has been already noticed, in connection with the condition of the fibrine; and stated to be often independent of the quantity of this constituent, and to be chiefly owing to the degree of nervous influence and vascular action. In the class of diseases now alluded to, the coagulum is not only remarkably soft, but, from the want of adhesion, and from the solubility of the colouring matter in the serum, is sometimes readily converted into a reddish fluid by slight agitation with it. In other cases no coagulum forms, the fibrine being suspended in small albuminous-like fragments in the serum, and the colouring matter precipitated to the bottom of the vessel. In several instances, these constituents are not separated from the serum, but seem combined with it; the whole mass remaining more or less fluid, and presenting a reddish, reddish black, or blackish colour, from the time of its emission till it furnishes evidence of decomposition. I have met, in other cases, with the blood changed into two parts: the upper and serous part consisting of a remarkably soft gelatinous mass, sometimes almost fluid, resembling very weak or uncoagulated calves-foot jelly, and forming from two thirds to four fifths of the whole: the colouring matter being spread over the bottom of the vessel, and presenting a dirty, black, and muddy appearance. I have also observed, and very lately, in two cases to which I had been called by neighbouring practitioners, the colouring part of the blood, with a portion of the fibrine and albumen, deposited on the bottom

of the vessel, of a colour between a deep brown and dirty dark grey, the serum being very abundant and turbid.

95. d. Appearances analogous to the above are also observed whilst the blood is in the veins of the dead body. In many cases, it is either fluid or semifluid, treacly, and of a dark colour. In others it is apparently decomposed and grumous; and in some, either consisting of perfectly fluid blood, or resembling water coloured with a reddish brown matter. In some cases, where the blood has been partially coagulated or separated into a grumous state, the more fluid parts, generally in the form of a bloody or sanious serum, have percolated the tissues, and escaped through the relaxed exhaling pores and extremities, and passed into the shut cavities; but more frequently flowed out on the mucous surfaces, leaving the more consistent parts of the blood in the vessels in larger proportion than in health. In all these cases, the blood, whether that drawn from the veins, or found in them after death, seems not so deficient of fibrine, as that its state is changed owing to exhaustion or annihilation of vitality, by virtue of the possession of which (derived from the influence of the organic nerves on the blood-vessels and internal viscera) its fibrinous corpuscles are aggregated into a coagulum when removed from the veins.

96. ii. FURTHER PROOFS OF CHANGE IN THE BLOOD, AND ITS RELATION TO PARTICULAR KINDS OF DISEASE.—A. *The existence of a buff on blood drawn from a vein has always been regarded by practitioners as a sign, not only of disease, but also of inflammation.* GENDRIN (following the path of his predecessors) asserts that the blood is in a *very inflammatory* state, when it coagulates quickly; is covered by a thick, concave, dense, elastic, buff, of a yellowish white; and separates into a truncated, ovoid, dense, elastic clot, floating in a serum, which bears a proportion to it of one and a half or two to one; is slimy, colourless, slightly turbid at the bottom of the vessel, and without any trace of colouring matter. The clot more rarely is of the shape of a truncated cone; is very dense at its surface, pretty soft at its base; does not float; and is more voluminous than the serum, which is of a pale yellow: in this case the blood is *more than very inflammatory*.

97. He observes that the blood is *inflammatory*, when the buff is thick, diaphanous, of a dull white, and covers a rather dense cylindrical clot, beneath which is the serum, yellowish, and equal at most twice the volume of the clot, a slight colouring deposit being found at the bottom of the vessel. If there be any buff when the blood is *sub-inflammatory*, the clot does not float, but is suspended in the middle of the liquid, or is precipitated, and is less dense than in inflammatory blood; the serum is slightly tinted with red at the bottom of the vessel, where a layer of colouring matter may be seen. But usually there is no buff; the clot is dense, ovoid, floating, and presenting a red stratum on its surface; the serum is viscous, limpid, somewhat turbid at the bottom of the vessel, where no colouring matter can be observed. The blood in this state coagulates quickly, and yields serum of at least twice the volume of the clot. When the proportion of serum is less than twice that of the clot, and the latter is soft, cylindrical, voluminous, although

floating, the blood is *scarcely sub-inflammatory*; it is so in a slight degree when the clot is dense, ovoid, and pendant in the middle of the vessel; when, of those two last mentioned coagula, the first occupies the middle, and the second the bottom of the vessel, the blood is *more inflammatory*.

98. This description is tolerably accurate, particularly as respects *inflammations of serous membranes, pneumonia, and other visceral inflammations*, when the circulation is free and the pulse not oppressed. But every one must have observed, that there may be very acute inflammation, and yet the blood is not buffed, particularly in children; and on the other hand, that this appearance often exists to a greater or less extent in *plethoric persons, in pregnant and puerperal females, in those who resort frequently to blood-letting, and in rheumatism* even in its least inflammatory forms. M. GENDRIN also errs as respects the rapidity with which inflamed blood coagulates. When the powers of life are unimpaired, and the circulation quick, and particularly during acute and general vascular reaction and vital or nervous excitement, coagulation is either longer in taking place, or, if it commences soon, it is much later in being completed than in other cases; but much will depend upon the stream of blood. If this be full, quick, and large, and the temperature of the apartment high, coagulation is delayed, and the buff more readily appears. If the stream be small, slow, and the temperature low, coagulation is rapid, and no buff is formed.

99. In some cases of *intense inflammation*, no buff appears, the blood coagulates slowly, the clot is less dense, and less serum is formed than in health; but the coagulum is very distinct from the serum, into which it does not at all dissolve. This, although another condition of the blood in a state of inflammation, is observed also in cases where the inflammation is not excessive, as every practitioner must have had numerous opportunities of ascertaining. Two superimposed layers of buff are sometimes seen—the one soft or friable, the inferior more dense, more compact,—but not (as is asserted) only when suppuration has taken place in an inflamed organ; still less must we receive as a sign of suppuration the dusky white or opacity of this buff, and the presence of a mucous stratum at the bottom of the serum. In short, it does not always happen that the buff shows itself on the blood in chronic phlegmasia, until the subject has become enfeebled, and the nutrition deteriorated. A repetition of bleeding, and a tendency to syncope, causes either a diminution, or the entire disappearance, of the buff. According to PLENCIZ, when the blood is not buffed in inflammations, the coagulum is always more firm than natural,—an observation which is tolerably correct in respect of the state of vital power, but not as regards the presence of inflammation. It should not be overlooked, that in many cases of very acute inflammation, particularly in its early stage, the nervous power may be so oppressed, and general vascular action consequently so imperfectly developed, that the coagulum will neither be firm nor exhibit any buff on the first and second blood-lettings; and yet, when this oppression has been removed, a firm and sily coagulum will be formed by the blood subsequently drawn. This is particularly the case when the respiratory func-

tion has been oppressed at the commencement of the attack.

100. Out of four and twenty cases of *peripneumonia* terminating fatally, Louis found the blood of nineteen of these patients covered by a buff, which was firm and thick at each bleeding in fourteen cases; soft, and sometimes infiltrated, in the others. It was cupped only in two fifths of the whole number of patients. The buff was absent in only six cases out of fifty-seven, which recovered. It was very thick, and cupped, in twenty-three of them. The blood was covered by only a slight buff in three cases out of five of *hydrocephalus*, softening of the brain, or *apoplexy*; and in another instance of softening of the brain, the blood remained semi-liquid, without clot or buff.

101. In four cases of *scarlatina, small pox, and measles*, which terminated favourably, the blood was covered by a thin and not very consistent buff; in one case of scarlatina it was firm and thick: of the same character in five cases out of seven of *erysipelas* of the face, and in four cases of *angina*, while in a fifth it was soft; in nine tenths of rheumatic patients it was equally firm and thick; in two subjects affected by *zona* it was not present. It was somewhat thick in four cases of *erythema*, where the circulation was considerably accelerated; and thin, in four out of fifteen cases of *pulmonary catarrh*. According to GENDRIN, the buff never appears on the blood of variolous patients, until after the eruptive fever begins; it is more strongly marked when the inflammation is more intense, and lasts even after desiccation has taken place. When buff appears at the very first, BAGLIVI is of opinion that the eruption will be considerable.

102. *B. Other states of the blood in various diseases.*—M. BOISSEAU states, that he has seen the venous blood of a lively red—now and then of a *clear rosy red*—and spouting in a transparent thread, in patients afflicted with inflammation of the lungs, and sometimes in those with inflamed joints. Among those with peripneumonia, but who were otherwise of sound constitution, he has noticed it covered by a *greenish buff*; yet the greater part of these patients recovered after repeated bleedings. In a very fine young girl, who had enjoyed good health, but was attacked by pain in the side in consequence of a chill, the blood was of a *dirty grey*, approaching to violet, and like lees of wine: after this bleeding she suffered no more, although her skin continued yellow for some months. M. BOISSEAU has also seen blood like *turbid wine* in several cases of pulmonary inflammation, which were nevertheless cured, the patient suffering little more in consequence of the unusual appearance in the blood.

103. In fact, the *hemorrhagic blood*, as also that taken from the veins of subjects attacked by *inflammation*, is not always consistent and buffed; it is sometimes found dissolved, thin, and serous. The latter appearance is, indeed, less common than the former; but sufficiently so to teach us not to attach too much importance to the aspect of the blood in inflammations, and also not to forget that, whatever may be its condition, phlegmasia will develope itself when the causes from which it springs are sufficiently powerful.

104. A *whitish appearance* of the venous blood has been long observed, arising from the presence of white flakes or streaks. This has been ascribed

to various causes; but with greatest truth to the existence in it of a large portion of unassimilated chyle. The separation of the blood into a soft or natural coagulum, and a milky serum, is much more common. This, as well as the foregoing state of the blood, has been imputed to various causes. EMMERT considered that it was owing to a substance analogous to buff. Some have ascribed it to milk; others to albumen; a few pathologists view it as owing to a matter analogous to fibrine; and several, as proceeding from the admixture of liquid fat. HALLER imputed it to liquid chyle. Of these opinions, the two last are the most accurate. There can be no doubt that both the milkiness of the serum, and the whitish streaks observed in venous blood, are owing in a great measure to unassimilated chyle; and the more accurate researches of modern chemists, particularly CHRISTIAN, BABINGTON, LE CANU, &c., have detected in this kind of blood an unusual proportion of oily matter. Dr. J. ADAM found oil in a pure state, and in considerable quantity, in the blood of a corpulent man, who had died suddenly in a state of intoxication. (*Trans. of Med. and Phys. Soc. of Calcutta*, vol. i. p. 74. and BURROWS, in *Med. Gaz.* July 12th, 1834.) This state of the serum is occasionally met with in various diseases, functional as well as organic; and seems connected with deficient assimilating power. SYDENHAM states, that he observed the blood drawn from a young convalescent to resemble pus,—an appearance probably owing to the great quantity of chyle carried during convalescence into the blood, which had been poor and defective, and to the circumstance of this fluid not having then experienced the process of sanguification. NICOLAS and GUENDEVILLE have noted, that the blood of *diabetic* patients contains an increase of serum, and very little fibrine; this serum contains, according to ROLLO, a saccharine matter; about the thirtieth part of what is found in urine, according to WOLLASTON.

105. During the prevalence of *scurvy* in Admiral Anson's fleet, the blood taken from the veins, after the eruption had appeared, was marked with dark or with vermilion streaks; on first issuing from the veins it was dissolved and very black, but after standing some time it thickened, and assumed a dark colour; no regular separation of its serum took place, and its surface was greenish in several places. When the disease had arrived at its third stage, the blood was as black as ink; and although it was kept several hours in a vessel, its fibrous part precisely resembled wool or hairs floating in a muddy substance. The blood issuing from the mouth, nose, stomach, intestines, or any other part, in the last stage of this malady, was entirely decomposed, black, or yellowish. It was found after death entirely dissolved in the veins, so that by cutting some branch of a rather large vein, it was possible to empty all the neighbouring branches with which it communicated of the yellowish black fluid they contained. The extravasated blood was of the same nature. In a scorbutic patient, opened by order of CARTIER, the cavities of the heart were stated to have been entirely filled with corrupted blood.

106. In four cases of *scurvy*, ROUFFE has found the right cavities of the heart filled with black and coagulated blood; and a greenish yellow polypus-like matter filling the left cavities of this organ,

the aorta, and the pulmonary artery and vein. Amongst the scorbutic subjects opened at Paris in 1699, by POUPART, it was found that in those who had died suddenly, the auricles of the heart were dilated by coagulated blood, the muscles loaded with black and corrupt blood, and the cellular sub-cutaneous tissue infiltrated by extravasated, black, coagulated, and congealed blood, in some cases, and by red blood in others.

107. BICHAT found in a dead body, instead of venous blood, a greenish sanies, which filled all the divisions of the splenic vein, the trunk of the vena porta, and all its hepatic branches; so that when cutting the liver, he distinguished by the flowing of this sanies all the branches of the vena porta from those of the hepatic vein, which contained blood in a natural state; this body was remarkable for such an excessive obesity, that BICHAT never remembered seeing any thing equal to it. Unfortunately he does not give us the symptoms of the disease of which this person died.

108. According to COYTER, GENDEIN, and many others, a black pulverised-like substance deposits itself at the bottom of the vessel containing blood taken from persons affected with *typhoid*, malignant and gangrenous diseases; the clot being often either completely dissolved, or not formed at all. I have seen these appearances, and various modifications of them alluded to above (§ 94.), not only in these diseases, but also in *hæmatemesis*, *dysentery*, severe infectious *erysipelas*, *phlebitis*, the dangerous forms of *puerperal* diseases, *puerperal mania*, and in *purpura hæmorrhagica*.

109. Remarkable fluidity of the blood is always observed after death from severe blows on the epigastrium, and from lightning. J. HUNTER states, that he has also found it fluid after death from a violent fit of passion. MCRAGNI observed it in a similar state after death from hunger; and M. AUDOUARD relates that it was uncommonly fluid in a man who died from *coup de soleil*, voiding blood from the mouth and nostrils. In two cases of *hydrophobia* I found the blood black; so fluid in the heart and veins, that it flowed out abundantly from the vessels of the head and neck, presenting an infinite number of oily points or particles on its surface; and when removed from the vessel, it did not afterwards coagulate. The same appearances were observed in a large proportion of the numerous cases described by M. TROLLET, and other authors on this disease. M. TROLLET states, that in several of his cases, a considerable quantity of gas escaped from the heart and aorta.

110. iii. THE CAUSES OF CHANGES IN THE HEALTHY STATE OF THE BLOOD.—The causes which occasion morbid changes in the state of the blood, are either such as are confined in their operations to individuals, or such as influence whole classes, or the community generally. They may thus be sporadic, endemic, or epidemic. In respect to their mode of operation, they may be arranged, 1st, Into such as vitiate the fluids from which the blood is formed; 2d, Into those which impede the functions of secretion and depuration; 3d, Those putrid or septic matters which contaminate the tissues and fluids to which they are applied, and act chiefly by absorption; 4th, Those which act upon the vascular system, either directly or indirectly, through the nerves which supply it; and,

5th, The passage into the blood of morbid matters formed in the same body that is the seat of disease.

111. *A. Of vitiation of the blood by the fluids which form it.*—The fluids which supply the waste of the blood are not infrequently vitiated, and thereby change the state of the circulating mass. The chief sources of this vitiation are hurtful or unwholesome ingesta. Many articles, even of food, will be hurtful when too long continued. The injurious effects of salt provisions on the blood, when exclusively employed, and particularly if depressing causes cooperate with this diet, are evident, and are fully illustrated in the article on SCURVY. The influence of diseased rye, in first changing the condition of the blood, and inducing a state of chronic arteritis, terminating in gangrene of the extremities, is also well known; and the effects of diseased or putrid flesh upon the system have been often noticed, although not always correctly traced to the quarters where the principal changes are produced. M. BERTIN states that a number of negroes in Guadalupe, having eaten the flesh of some animals dead of an epizooty, were seized with fever, and violent ileus, of which the greater number died: and numerous cases are on record, where persons shut up in besieged towns, having partaken of putrid animal matter, or of the flesh of animals that have died, have been seized with malignant states of disease; and the blood has been found fluid, dissolved, blackish, grumous, &c. upon examination after death. In these, and numerous similar instances which might be adduced, although the state of the blood has been alluded to in general terms, the information has been deficient in precision, and has been furnished incidentally, the attention of the observer having been directed to other quarters.

112. M. MAGENDIE adduces, in his Journal, the instance of a man, who, after a long use of vegetables in which the oxalates abounded, underwent the operation of lithotomy, and a large oxalate of lime calculus was removed from him. We know that a large proportion of both our mineral and vegetable medicines operate by being absorbed into the circulation (see art. ABSORPTION, &c.); and there is every reason to suppose that various morbid or foreign matters may pass with the chyle into the blood, and modify its condition. The excessive or long-continued use of alkalies, or of alkaline salts with excess of base, has the effect of diminishing the cohesion and the viscosity of the blood, and of preventing it from coagulating after it has been removed from the vessels; and while these substances thus, as it were, dissolve, or attenuate this fluid, they also diminish the vital cohesion and tonic contractility of the extreme vessels, and of the tissues, and create a disposition to extravasation of blood in the parenchyma of the organs, and to exudation of it from the mucous surfaces. On the other hand, the acids—particularly the mineral acids—turpentine, the acetate of lead, and all the salts,—especially those with excess of acid—have the effect of increasing the healthy crasis of the blood, and of producing an opposite change to that now stated. When used in excess, however, or injected into the veins, they have been conclusively shown to give rise to fibrinous concretions in the vessels, to coagulate the albumen of the blood, to darken its colour, and thus to render

it grumous, and unfitted for circulation through the minute capillary vessels, particularly those of the lungs. The influence of salted provisions, long and exclusively employed, in which the soda is generally in excess, in attenuating the blood, in preventing its coagulation when removed from the vessels, and in relaxing the soft solids; and the effect of acids in removing these morbid states, are well illustrated by the nature, progress, treatment, and prophylaxis of scurvy.

113. That the nature of the food materially affects the state of the blood is further shown by the general character of the diseases most prevalent in various communities, living chiefly on certain kinds of aliment. The inhabitants of several places in the north of Europe, who live principally on *fish*, a large proportion of which is usually kept until it has become remarkably stale, or even ammoniacal, from incipient decomposition, who seldom partake of flesh meat unless in a similar state of change, and who dry or smoke both these kinds of food, instead of salting them, are generally subject to diseases which arise from, or are connected with, an impure state, or weak cohesion, of the circulating fluid. It should not, however, be overlooked, that the more complete changes which respiration effects on the blood in cold climates, and the active exercise of the functions of depuration, under the influence of the vital energies, serve to counteract the morbid alterations which this cause would induce. Yet still the prevalence of disorder in these eliminating organs, particularly the mucous and cutaneous surfaces, which preserve the purity of the blood; and the marked disposition, which all febrile diseases evince, in persons thus circumstanced, towards vitiation of the circulating fluid; and the consequently low or adynamic symptoms which characterise their progress and termination; are sufficient indications of a change in the constitution of this fluid. It is worthy of notice, that communities which live in the manner now alluded to, generally employ remarkably acid beverages, usually consisting of the fermented whey of butter-milk, and a fermented farinaceous infusion. I believe that nothing could be used as common drink better calculated than these to counteract the ill effects of their diet on the blood. Besides the acid existing in these beverages, they also contain much carbonic acid gas, which likewise contributes to their wholesome influence on the blood.

114. The effects of living upon much fresh animal food, in increasing the quantity of fibrine, in rendering the blood rich and abundant, and in disposing to inflammatory diseases, are too well known in all their relations to require illustration. But when we consider the influence of various kinds of aliments in modifying the state of the blood, we ought never to overlook that, as its organisation and vital manifestations, commence with the chyle, and depend upon the vital condition of the vessels and tissues, and upon the perfect discharge of all the functions which contribute to its formation and purification, the extent of mischief produced by unwholesome food will be commensurate with the deficiency of vital energy, and the imperfection of the various organic functions. A person of a robust constitution, breathing a pure air, and assisting the eliminating functions by regular exercise, will suffer much less, than the debilitated, the indolent

and those placed in unhealthy localities, from either unwholesome food, or from the accidental ingestion of injurious substances. A person thus circumstanced will also suffer less from the habitual indulgence in too much animal food; but more commonly such indulgence will give rise to a superabundant secretion of uric acid, and favour gravel. In such persons, also, there is reason to suppose that urea, or uric acid, may exist in the blood, and be deposited from it in various parts of the body, particularly the small joints. The uric acid, which becomes thus abundant, is a highly azotised animal principle, obviously formed from the excessive use of food which abounds in azote; and when its appropriate emunctory, the kidneys, fails of carrying it out of the blood, it and its combinations are secreted in other parts.

115. *B. Imperfect performance of the functions of depuration, a chief cause of morbid states of the blood.*—The evident influence of this class of causes renders it a matter of surprise that it has been so long overlooked in our estimation of the causation of disease. When the facts which have been brought to light by the successful investigation of the animal functions are duly weighed, and estimated in connection with the sources of impurity to which the circulating fluid is exposed, the importance of assigning a due rank to this kind of morbid agency will become manifest. When we consider the important changes that take place in the lungs—the quantity of carbonaceous fluids constantly discharged through this organ, and of watery vapour loaded with various impurities continually exhaled from its surface, and passing out with the expired air; or the abundant perspiration, sensible as well as insensible, constantly issuing from the cutaneous surface, and holding dissolved in it substances which require to be eliminated from the circulation, owing either to their excess or their foreign and hurtful nature; or the varying state of the urinary secretion, the quantity eliminated and the changes it manifests from variations of temperature, atmospheric moisture, and especially from the abundance and nature of the ingesta; or the discharges which the female experiences during the greater part of her average duration of life; or the secretions formed by the liver, the internal surface of the bowels, the pancreas, &c. out of elements which, if not combined into these new forms, and destined to ulterior purposes, would become poisonous to the frame, by vitiating the blood; it must be evident that an interruption to any one of these several functions, if not compensated for by the vicarious increase or modification of some others, must be followed by alterations of the quantity, of the quality, of the relative proportion of the constituents, and even of the vitality of this fluid.

116. *a.* Under the due dominance of the vital energy of the system—and particularly of that influence exerted by the organic nerves on the great secreting viscera, and on the whole vascular system—no sooner does any substance, which may have been carried into the circulation, or accumulated in it, become injurious, than it is eliminated by the appropriate action of some organ, which often evinces a kind or degree of disorder, either in its actions, or in the state of its secretions, according to the nature of the substance which affects it. Thus, we perceive various substances

and kinds of food, even in health, affect the actions and secretions of the kidneys, of the skin, and of the bowels; certain of their constituents becoming sensible in the halitus of the expired air, in the perspiration, or in the urine, where they could be transported through the channel of the circulation only. The fœtor, &c. of the breath, and of the perspiration, &c. consequent upon interruptions of the abdominal secretions, also indicates that impurities have accumulated in the circulation, and that they are being eliminated by means of the lungs and skin. So long as the vital energy is sufficient for the due performance and harmony of the functions, injurious matters are seldom allowed to accumulate in the blood to the extent of vitiating its constitution, without being discharged from it by means of one or more organs; but as soon as this energy languishes, or is depressed by external agents and influences, and the blood is thereby either imperfectly formed, or insufficiently animalised and depurated, some one of its ultimate elements or proximate constituents becomes excessive, and the chief cause of disorder, which terminates either in the removal of the morbid accumulation, or in a train of morbid actions and organic lesions. These very important pathological facts are so fully proved by the history of the most prevalent and serious diseases, and by their terminations and results, and are so perfectly unopposed by accidental or occasional exceptions, that proofs or illustrations of their value and uniformity are superfluous.

117. Thus it will appear that, although changes in the secretions and in the blood itself are most influential in the production, perpetuation, and aggravation of disease; yet such changes are prevented, controlled, and even in some cases promoted, by the state of the nervous energy and vital actions of the frame; to which influence they are always more or less subject, unless when the causes of the disorder are so intense, in relation to its state, as entirely to annihilate it, as is occasionally remarked in respect of the most pestilential diseases, and of the operation of some virulent poisons. Thus, also, will it appear, not only that hurtful matters carried into the circulation, and ultimate elements, or proximate constituents allowed to accumulate in it, owing to the imperfect performance of some eliminating function, will be removed from it, when the vital influence is sufficient for the task; but that both kinds of injurious agents will, according to their natures, become productive of a vitiated state of the blood, of the secretions formed from it, and even of the various tissues themselves, when the state of vital manifestation, particularly as displayed in the organic nerves, is insufficient to remove them from the frame, or to control their combinations, or to direct them to salutary changes.

118. Before leaving this important subject—important in as far as it involves the fundamental doctrines of disease, and points to rational indications of cure—I may briefly illustrate it by a reference to two or three facts, which are of every day occurrence. It has been long known that affections impeding the functions of the lungs are frequently attended with an increased secretion of bile. This I have shown to depend upon the liver being excited to increased action by the carbonaceous and other elements accumulated in the blood, owing to their elimination by the lungs

being interrupted; and thus we readily recognise the cause of the frequent complication of biliary disorder with pulmonary disease, particularly in some hot countries. In cases also, where, owing to asphyxia, or to disease, as pestilential cholera, &c., the requisite changes by respiration are not effected in the blood, if recovery take place, the diseased states of the secretions of the liver and bowels indicate that the favourable result has been chiefly owing to the increased performance, under the influence of life, of the functions of these organs. When death occurs from asphyxia, and particularly if it be occasioned by the vapour of charcoal, the black, fluid, or dissolved state of the blood, the presence of yellowish globules like oil, sometimes observed on its surface, and noticed by M. RAYER, sufficiently indicate the changes produced in this fluid, and the influence these changes exert on the chief functions; and if recovery is effected, the evacuations evince that the principal secreting organs have been the means of removing the morbid matters from the blood. A strict inquiry, also, into the changes which precede a favourable termination of the latter stages of malignant diseases, manifestly detects the influence of the secreting and eliminating organs in bringing about this result, and chiefly by their operation, under the influence of life, upon the blood.

119. *b.* That high ranges of *temperature* occasion very important changes in the state of the blood, had been remarked by several of the ancients, and by some of the best writers of the eighteenth century; but the chief mode of its operation was first pointed out in a thesis written by me in 1815. I there showed that increased atmospheric warmth, particularly when accompanied with moisture and miasmatic exhalations, greatly diminish the changes effected during respiration on the blood in the lungs; and that the carbonaceous, and other elements and impurities, are imperfectly discharged from the blood through this channel. I further showed, both in that production, and in my physiological notes, that these materials are partly combined to form bile, thus occasioning an increased as well as vitiated secretion of this fluid, and partly excreted by the mucous surface of the intestinal canal, and by the skin; and that, if the functions of these organs, — the liver, skin, and intestinal mucous surface, — which thus compensate the diminished actions in the lungs, be at all impeded under such circumstances, the elements, which they should have eliminated from the blood, necessarily accumulate in it, and influence the functions of the nerves ramified on the blood-vessels, and of the principal secreting organs and surfaces, ultimately vitiating the blood and all the soft solids of the body, when the vital energies become depressed or exhausted, and the train of morbid phenomena experiences no change tending to health.

120. Thus, we perceive that, during high ranges of temperature, particularly when the air is loaded with miasmata, and the liver is inactive, the elements of the bile will accumulate in the blood, sometimes even to the extent of giving the countenance a darker or more dusky tint than natural, and the blood will be changed, 1st, by the superabundance of the materials whence bile is secreted; and, 2d, by the passage of this fluid, or of certain of its constituents, into the blood, after its secretion has taken place. In the foregoing man-

ner (§ 119.), I explained the prevalence of biliary disorders, particularly bilious cholera, diarrhoea, dysentery, increased secretions of bile; and, in warm climates and seasons, and when vegetable and animal miasms are superadded to this influence, the occurrence of fevers of various kinds — remittent or continued, simple or complicated, biliary or malignant, inflammatory or dysenteric, endemic or epidemic, sporadic or pestilential — according to the circumstances of individuals, the kind of locality, the nature, combination, and source of the miasm, and the state of the atmosphere. This doctrine, now many years since contended for, later experience, and the concurrent opinions of more recent observers, have fully confirmed. (SEE FEVER.)

121. *c.* Several states of disease, which occur in the puerperal state, may be referred to the arrest of the secretions or discharges incidental to it. The secretions from the internal surface of the uterus, and which partly consist of the bloody serum poured into the uterine cavity from the open mouths of the vessels which communicated with the placenta, are not infrequently arrested or impeded. In such cases, the blood does not undergo that salutary depuration which this evacuation occasions; and, consequently, either experiences further disorder, or it creates a disposition in the system to the invasion of other causes of disease. Besides, the fibrinous and albuminous parts of the blood, which are generally in excess during pregnancy, not having been discharged by this route, determine the occurrence of inflammation of the uterus, peritoneum, &c. upon the co-operation of exciting causes. Or, if such causes have produced these diseases, the obstruction or interruption of the secretions and discharges, which is generally thereby occasioned, aggravates the mischief, and the *post mortem* appearances often furnish more or less evidence of the suppression having been concerned in modifying the results; the matters poured out from the diseased parts frequently resembling, or containing constituents of, the secretion which was suppressed. How are we to account for this? We find it demonstrated, that the materials of both bile and urine, owing to obstruction of these secretions, may be mixed with the blood, and give rise to certain well known symptoms. We may therefore extend the same principle to suppression of the puerperal secretions; and infer, that the matters which constitute them, having accumulated in, or not been eliminated from, the blood, are discharged along with those effusions of albuminous serum which frequently follow the diseases of this state, even although they may not actually be the causes of these diseases.

122. GRAEFFE of Berlin (*Rev. Méd.* Jan. 1827) states, that a female, in a favourable state, and suckling her child, experienced a fright on the eighth day after delivery, which occasioned a complete suppression of her milk. Febrile excitement followed, and effusion took place in the peritoneal cavity and cellular tissue. Upon tapping a few weeks afterwards, a bucket of fluid, resembling whey, and exhaling an acidulous odour, was drawn off. Upon being boiled with dilute sulphuric acid, it furnished a substance resembling caseum. When tapped six weeks afterwards, the fluid was of a greenish yellow, and without the least trace of caseum.

123. That changes in the composition or state of the blood are also followed by alterations of the natural secretions, is fully shown by both physiological and pathological facts. It is not, therefore, unreasonable to suppose, that modifications or changes of morbid secretions will be occasioned by a similar cause. Indeed, alterations of the latter are quite as likely to be the consequence of pathological conditions of the blood, as changes of the former.

124. *d.* In cases, where the functions of the skin, or of the kidneys, are interrupted, not only are the watery parts of the blood frequently increased, but also various irritating matters accumulate in it, unless eliminated by other organs. These excite more or less disturbance of the whole vascular system; and if the cause continues, or is assisted by concurrent causes, the blood itself becomes very evidently changed, in respect both of the state of its eror and of its serum. The effects of obstruction of the bile on the blood, and mediately on the tissues, are sufficiently apparent to the sight; and the actual presence of this fluid in the circulation, or, at least, the peculiar matters which characterise it, has been shown by several modern chemists, and completely demonstrated by the recent researches of MM. PROUST, ORFILA, GMELIN, and LE CANU. But it is unnecessary to prosecute the subject further, as I consider the grand pathological inference to be fully established — *that the interruption or obstruction of any important secreting or eliminating function, if not compensated by the increased or modified action of some other organs, vitiates the blood more or less; and, if such vitiation be not soon removed, by the restoration of the function primarily affected, or by the increased exercise of an analogous function, that still more important changes are produced in the blood, and ultimately in the soft solids, if the energies of life are insufficient to expel the cause of disturbance, to oppose the progress of change, and to excite actions of a salutary tendency.*

125. *e.* ILLUSTRATIONS.—The importance of this conclusion will become still more manifest, if we illustrate it by reference to the pathology of fever, and observe the train of morbid phenomena produced by its causes. These, although modified even still more infinitely than the combination of causes in which they originate, present the following almost unvarying characters and mode of progression:—A person exposed to the miasmata generated from vegetable or animal matter in a state of decay, or from persons affected with fever, inhales such miasmata into the lungs, where they produce a morbid impression on the nerves of organic life, followed by depression of the vital influence: the functions of digestion and secretion languish, and, owing to the imperfect performance of secretion and assimilation, the necessary changes are not fully effected in the blood; and thus irritating or otherwise injurious matters accumulate in it. These phenomena generally proceed gradually, until, owing to the continued and augmented depression of the vital powers throughout the frame, and the increasing change in the state of the blood, marked disorder is occasioned. The vascular system becomes excited by the quantity and the quality of its contents; and, when the vital energies are not too far depressed for its production, the excitement becomes general. The accelerated circulation tends still more to

disorder the state of the blood; but it also has the effect, in the majority of cases, of exciting the organic functions, of restoring the secretions which were impeded or interrupted, and thereby of removing the morbid state of the circulating fluid; after which the return to health is rapid. When, however, salutary reaction of the vascular system is not brought about, owing to the morbid depression of the vital energy, and to changes which had taken place in the blood; or, if reaction occur, but, owing to the state of this fluid, and of the nervous influence to which it is subject, it is irregular, imperfect, or excessive; the vitiation of the blood proceeds; the secretions are also vitiated; the solids affected; one or more vital organs suffer in an especial manner; the energies of life are exhausted; and various organic lesions are induced, having reference to the previous state of the system, the kind of change produced in the blood, and the agencies in operation during the progress of disease.

126. Such is the general procession and character of the morbid phenomena; and we observe in them certain prominent features, by means of which the various species of fever are recognised. They may be briefly stated to be, — 1st, The impression of the causes on the nerves of organic life, the depression of their energies, and imperfect performance of all the functions which they influence: 2d, More or less vascular excitement or change in the state of vascular action, and of the circulating fluid: 3d, Frequent predominance of disorder of some one general system, or vital organ: 4th, Consequent exhaustion, with either a gradual restoration of the functions, followed by a return to health; or more marked vitiation of the blood, of the secretions formed from it, and of the solids of the body, often terminating in organic changes, or death.

127. Here we observe *three* different states of vital action, in each of which the blood generally presents very different appearances. 1st, *The state of depression and invasion of fever*, in which the blood taken from a vein is of a very deep or dark colour; flows with difficulty; frequently occasioning syncope, or great depression upon the loss of a few ounces; and generally coagulates rapidly, and separates into a very dark, large, and soft coagulum, which falls low in the serum—the quantity of which is extremely small in proportion to the clot. Not infrequently the separation is very imperfect, and the coagulum extremely large and soft. 2d, *The state of reaction, or febrile excitement*, in which the blood flows more freely from the vein, and of a brighter colour, occasioning little immediate depression until a more considerable quantity is abstracted; is apparently thinner than natural; coagulates much more slowly, and separates into a somewhat more firm coagulum, than in the former state of disease; and occasionally exhibits a thin fibrinous layer on its surface: in several malignant cases, however, even in this stage, either the separation of serum is very imperfect, consisting chiefly of a deep gelatinous layer, beneath which the colouring matter is deposited in an extremely loose state, and dark colour; or the blood remains imperfectly coagulated, and of a gelatinous consistence. 3d, *The state of exhaustion*, in which the blood generally flows readily; but is uncommonly thin, dissolved or attenuated, and dark coloured; occasions great increase of exhaustion; and either

scarcely coagulates, or separates into a remarkably loose coagulum, which lies at the bottom of the vessel; the serum varying much as to quantity and colour; being often turbid, clouded, watery, or slightly viscous, and less saline in its taste. Sometimes the coagulum which falls to the bottom of the vessel is so loose, that it appears as a precipitation of the colouring matter, of a very dark colour, and is readily stirred up into the supernatant serum (§§ 94. 108.). In nearly all the cases where I have seen blood taken, either in the state of depression or in that of exhaustion, but particularly in the latter, either little or no fibrine could be collected from the coagulum; or what was obtained was scanty, remarkably loose, and even flocculent, and nearly albuminous. Throughout the progress of typhus, the venous blood is generally watery, and without consistence,—a fact to which my attention was called many years ago by the late Professor HILDBRAND, at Vienna. In the latter stages of typhoid or malignant fevers, it seems nearly altogether deprived of fibrine. In two or three cases, the blood was abstracted in these states chiefly with the view of examining its appearance. But several instances have occurred to me, in which I have found that blood had been drawn, although the nature of the symptoms, and the state of this fluid, equally contra-indicated the propriety of the practice.

128. With respect to the *post mortem* appearances of the blood in the vessels, I stated, many years ago, when describing the symptoms and morbid appearances of yellow fever, several cases of which I had an opportunity of examining within five hours after death, in the years 1816 and 1817, that it is generally half dissolved, or fluid and grumous, dark coloured, and speedily undergoes complete decomposition. (*Quarterly Journ. of Foreign Med.* vol. ii. 1820, p. 446.) A similar state of the blood has been noticed by AREJULA, BALLY, PALLONI, and others, in the epidemic yellow fever of Spain; and more recently by Dr. STEVENS, who has described the appearances of the blood in tropical fevers with greater minuteness than his predecessors, has referred to most important changes of the saline constituents of this fluid, and has fully confirmed some very detailed observations adduced by myself several years previously (*Appendix to M. RICHERAND'S Physiology*, p. 640. *et seq.*), comprising the general results obtained from noting the appearance of the blood in a number of febrile and malignant diseases. Dr. STEVENS states (*Paper read to the College of Physicians in May 1830*), that the blood, in these fevers, loses its property of coagulating, because more fluid, and thin or watery, of a much darker colour, and has its fibrine and saline ingredients exhausted,—changes which I have ascertained to obtain in a greater or less degree in the fevers of this country, particularly in their latter stages, and have described in my lectures since 1825. (See FEVER.)

129. Besides other proofs of the diseased state of the blood in fevers, I may adduce the following:—In those who were victims to malignant fevers, CHIRAC found the blood in the ventricles of the heart, and the vena cava, more or less clotted; and all the ramifications of the vena porta were filled with grumous blood. In those who died of typhus, at Brest, in 1757, the blood was found grumous, unnatural, black, and decomposed, par-

ticularly in the liver. SOULIER observed blackish blood coagulated in the vessels; and extremely fœtid black blood in the stomach, of those who fell victims to the plague at Marseilles. LARREY found the blood black and liquid in those who died of the plague in Egypt. After intense fevers, ANDRAL has found the blood contained in the heart, and in the larger arterial and venous vessels, remarkable for its great liquidity, and its black and deep colour: in some subjects it presented a clear rosy tint, and was like water coloured red; some small fibrous grains were then dispersed over the internal surface of the vessels. In one individual, the liquid contained in the larger vessels was no longer really blood, but a matter the colour of wine lees, sanious in some parts, nearly resembling the ill-elaborated fluid contained in unhealthy abscesses.

130. M. BOUILLAUD found, in two or three cases, the blood clear and rosy, after putrid fevers; but it nearly always appeared blacker and more liquid than in its normal state: this alteration varied, from the degree in which the clot was simply flabby, to that in which the blood formed only a blackened and liquid mass, without any trace of clot. This blood, being put into a basin, was brilliant, shining, and full of micacious specks; in some cases it has been found mixed with purulent matter, or pure pus; at other times it was so altered and disorganised that it resembled a putrid mass. BOUILLAUD justly adds, that in such instances it is not rare to meet with a quantity of gas, more or less considerable, in the circulating canal; and also that, although it be difficult to describe these changes, they should nevertheless be taken into consideration, if we wish to explain satisfactorily the phenomena attendant on putrid fever.

131. The malignant febrile diseases which very frequently attack horses and cattle are always attended with a remarkable alteration of the blood, even early in their progress. These diseases are less frequently met with in this country, than in marshy and warm climates. In some of the most pestilential of these climates, horses cannot be reared; and when brought thither, they generally experience a febrile attack, with adynamic or malignant symptoms, and speedily die. This is constantly the case in some parts of Africa, where the vegeto-animal miasms from the soil are abundant and concentrated. I had an opportunity of observing the examination of a horse brought from the interior to an unhealthy situation on the coast, where it died, as all others had done, a few weeks afterwards. It was not much emaciated; but the blood was black, decomposed, fluid, and sanious; and the liver, spleen, lungs, heart, and, indeed, all the internal viscera, softened, ecchymosed, and lacerable with the utmost ease.

132. C. *Contamination of the blood by putrid or septic matters applied to the tissues.*—These substances were not inappropriately said, by the older writers, to occasion a putrid ferment in the part to which they were applied. The ferment may be disputed, but that they produce change of the blood is undeniable. If we examine the subject closely, we can arrive at this conclusion only,—that the substance applied changes the part to a state somewhat similar, as respects sensible properties, to itself; and that this contamination soon extends, either by its immediate effects upon

the organic nerves supplying the vessels, and consecutively on the blood, or by the direct introduction of the contaminating matter into the divided vessels, or by its imbibition or absorption, or by one or more of these channels, to the whole body, affecting, more or less, the blood, the secretions, and the solids. That these changes take place is undeniable, although the precise channel of primary infection cannot be easily demonstrated; and is sufficiently proved by the facts already adduced (§ 92.), and by those which follow (§ 133.). The instances of gangrenous or diffusive inflammation of the cellular tissue, arising from contact or inoculation of putrid animal matter, as recorded by numerous writers, and recently by Drs. BUTLER and DUNCAN; the not infrequent instances of it from injury in the dissecting-room (see CELLULAR TISSUE, *Diffusive Inflammation of*); and the occurrence of putrid fever, with gangrenous pustules and carbuncles, particularly amongst farriers, flayers, and knackers; furnish proofs and illustrations of the blood being one of the chief, although, perhaps, not the primary or only, channel through which the whole frame becomes more or less infected in a large and important class of diseases. A most remarkable instance of this, and at the same time showing to how great an extent the fluids and solids of the body may be contaminated, and yet the patient recover, is recorded by M. GENDRIN.

133. A flayer was affected with putrid fever, and gangrenous pustules and carbuncles. His breath, evacuations, and whole body, were horribly foetid; and blood taken from a vein was, three hours and a half after its emission, unusually dissolved and black; and gave out an odour resembling that of putrid flesh. A spontaneous discharge of a black, dissolved, sanious blood, also occurred from his mouth and nostrils. M. GENDRIN introduced some of the blood taken from the arm of this person into the cellular tissue of a cat, and into the femoral vein of a dog. Both animals evinced symptoms of putrid fever, and died in a few hours. The blood throughout their bodies was dark and fluid; the heart soft and flaccid; the viscera congested, and ecchymosed with dark spots, and speedily began to exhale a foetid odour. M. GENDRIN also details some experiments, in which he injected into the veins of different animals, the blood of persons affected with confluent small pox. Very violent effects, rapidly terminating in death, followed; and, upon inspecting the bodies, several viscera were found highly inflamed and congested.

134. *D. Contamination of the blood from causes influencing the state of the vascular system, either directly, or mediately through the nerves which supply it.*—Under this head may be comprised a very numerous class of causes; and, indeed, many of those which were alluded to in preceding sections may also act in this way. *a.* Infectious and contagious miasms and secretions may change the state of the blood in a more or less direct manner, as well as by first affecting the organic nervous system generally, and thereby impeding or changing the action of vital and secreting organs. Inordinate acceleration of the circulation appears to be frequently followed by serious alterations of the blood. The experiments of M. DUPUY on several animals show that the fibrine is either very much diminished, or otherwise changed, by

their being coursed or hunted; as the blood remains fluid, or becomes dark coloured and grumous subsequently: M. CHAUSSIER found that a portion of blood altered by this cause produced gangrenous pustules and malignant fever, when inserted into the cellular tissue of sound animals; and the striking instance recorded by DUHAMEL, and already alluded to, further proves that a morbid state of the blood is occasioned by over-driving animals. HALLER and BUCHNER remark, that vehement exertion renders the urine foetid, acid, and scalding; the perspiration foetid and disagreeable; the blood very fluid, acid, and vitiated; and, if long continued, occasions most ardent fever, terminating rapidly in death, and dissolution of the fluids and solids. HALLER refers to two cases where he observed these effects produced by intense acceleration of the circulation by running; and adds, that the blood of hunted animals is often not only fluid, but foetid; the flesh becoming quickly putrid. The attenuation and subsequent alteration of the blood observed in ardent or other fevers, attended with inordinate vascular action in their early stages, and the ecchymosis, petechiæ, softening of the mucous tissues, &c. may doubtless be attributed, in part, to the rapidity of the circulation, or increased motion to which it is subjected. If we continue to agitate healthy blood as it flows from a vein, it becomes thinner than natural, a small portion of fibrine collects around the stick with which it is stirred, and the blood remains fluid, as must be familiar to every one, and long since demonstrated by SCHWENCKE.

135. *b.* If any of the neutral alkaline salts, particularly those with excess of base, be added to blood as it is discharged, the coagulation will either be entirely prevented, or imperfectly produced; little or no fibrine will be formed, and its colour will become more florid. These facts have long since been noticed by VERHEYN, ELLER, RUTTY, HALLER, &c. The injection of acids, or the metallic salts, particularly those with any excess of acid, renders the blood dark coloured, and changes it into a grumous fluid, from partially coagulating its albumen and fibrine. The experiments of ELLER, GIANÉLLA, DUHAMEL, FRIEND, COURTEN, RUTTY, DE HUYDE, SPROEGEL, AALSEM, BOBRICH, PETIT, and various others, prove this effect; and further show, that when these substances are added to blood taken from a vein they either accelerate its coagulation, rendering the coagulum firm; or, if strong solutions are employed, the coagulation is irregular, the separation of the watery portion is more perfect, and the coagula are of a dirty black or dark brown colour. The attenuating effects of the fixed and volatile alkalis, and of their carbonates, both upon the blood and the secretions formed from it, particularly when long employed, will be considered as proved by any one who will peruse the experiments of SCHWENCKE, FRIEND, ELLER, RUTTY, COURTEN, PITCAIRNE, THACKRAH, and SCUDAMORE, without the bias of system; and they are confirmed in my mind by some observations I have made of the results when these substances are mixed with blood immediately after venæsection, or when exhibited internally in large doses for some time previous to abstraction of the blood: whilst directly opposite effects are observed to follow the internal use of acids. In the

latter case, the coagulum is firm, the blood of a deep or dark colour, and the fibrine abundant: in the former, the blood is thin, of a brighter colour, the coagulum much less firm, and the quantity as well as the cohesion of the fibrine diminished.

136. The effect of the fluid extract or tincture of opium, alcohol, tonic or astringent tinctures, and of spirits of turpentine upon the blood, is to increase its coagulability; and, when injected into the veins in sufficient quantity, to produce death, as in similar experiments with acids and the metallic salts, chiefly from this mode of operation. The experiments of COURTEN, FRIEND, YOUNGE, SCHWENCKE, DE HEYDE, SPROEGEL, SILBERLING, and FONTANA, fully prove these facts. The accuracy of the results as to one of these substances, has been confirmed by the experiments of the writer. That both alkalies, acids, and salts, act upon the system chiefly from their being absorbed and carried into the blood, has been satisfactorily demonstrated by MAGENDIE, TIEDEMAN and GMELIN, MEYER, WESTRUMB, and various others, and will not be now doubted, although the active exercise of the eliminating functions, which their very presence in the blood generally promotes, prevents their accumulation there to any considerable or deleterious extent, unless they have been taken in poisonous doses. They have, nevertheless, been absorbed in such quantity as to be detected both in the blood and in the various secretions by means of chemical agents, as demonstrated by MM. GROGNIER, CHAUSSIER, ORFILA, and by BUCHNER, KRIMER, BENNERSCHIEDT, SCHUBARTH, and Dr. O'SHAUGHNESSY.

137. c. The interesting researches of MM. GASPARD and MAGENDIE, in order to ascertain the effects of *putrid vegetable* and *animal matter* when introduced into the cellular tissue or injected into the blood, further illustrate the importance that is to be attached to morbid states of this fluid, as well as the origin and nature of various diseases. These physicians have fully proved that such substances, when thus employed, produce symptoms very similar to those of yellow fever, and typhus; and that, after death, this fluid is found remarkably altered, being nearly altogether fluid, of a very dark colour, and partially exuded from the capillaries, both into the parenchyma of the viscera, and from the mucous surfaces. That the blood is really altered in its nature by this inoculation, is proved not only by those changes, but also by the circumstance of its having lost the power of coagulating upon removal from a vein soon after it has been thus infected, and by its speedy putrefaction. The more recent experiments of MM. LEURET and HAMONT furnish the like results; whilst those performed by M. MAGENDIE show that dogs confined over, and breathing the effluvium proceeding from, animal and vegetable matters undergoing decay, experience similar symptoms to those now referred to, and the same alterations of the blood, of the secretions, of the excretions, and of the viscera, as observed in yellow fever: and, in all these cases, the morbid changes also extend more or less to the soft solids, and particularly to the mucous surfaces, the lungs, the liver, the heart, &c.

138. A most interesting fact has been stated by M. LEURET, and one which fully illustrates

the views I have entertained respecting the nature of certain forms of *puerperal fever*. This physician injected some blood from an artery of a living horse affected with gangrenous boils (*pusculæ malignæ*) directly into the veins of a mare five months with foal. She died five days afterwards. The heart, lungs, and intestinal canal were studded with dark ecchymoses, the uterus was gangrenous, and the blood dissolved and dark-coloured. But, in all the cases where poisoning has resulted from the injection of septic or putrid matters into the circulation, or from virulent, and rapidly fatal poisons, it must not be overlooked that, although the more manifest lesions are often observed in the blood, the injurious agent affects also the organic nerves terminating in the vessels, and consequently the vitality of the vessels themselves, altering the blood they contain, and thereby ultimately contaminating all the secretions and solids of the body; and that the mode of operation of the greater number of these septic agents, whether applied in an aggregate or palpable form, or from being dissolved in the moisture of the air, is very different from that of the saline and mineral substances considered above, which affect the blood more especially. (See INFECTION.)

139. d. The direct influence of the nervous system upon the blood was long since contended for by BARTHEZ, and admitted by several physiologists, the chief error, or rather mischievous fallacy in their theory, however, being, that this influence was imputed to the cerebro-spinal nerves, and not to the ganglial nerves, to which it almost entirely belongs. This great mistake also vitiates the opinions promulgated on the subject by Mr. BRODIE and Dr. W. PHILLIP. The opinions which I have entertained, and frequently expressed, that the power exerted by the nervous system on the blood is limited to the organic or ganglial class of nerves, and that their functions are very distinct from those performed by the cerebro-spinal class of nerves, the influence of the former having been too generally and erroneously imputed to the latter, have been already alluded to. Since their promulgation many years ago, numerous proofs of the accuracy of these views have been furnished in different countries. That the effects produced by the organic nerves take place chiefly in the minute vessels may be safely assumed; and that a reciprocative influence is exerted by the blood upon these nerves will not be denied; but it may also be inferred that the effects produced by the organic nerves are not limited to the small vessels. Professor MEYER's experiments support this opinion. He found that, when both pneumogastric nerves were tied, the blood coagulated in all the pulmonary vessels, the colouring matter having separated from the fibrine; and that this change was not the consequence of death, but its antecedent, since it was uniformly found upon opening the bodies the moment they expired. M. DUPUYTREN had previously ascertained, that a simple division of the pneumogastric nerves prevented the venous from being converted into arterial blood in the lungs.

140. M. DUPUY found that, when the pneumogastric nerves were divided in the cervical region, in horses, the quantity of fibrine in the blood became progressively diminished to a very

remarkable extent; and that a similar result followed laborious breathing in disease. He further states, that the blood throughout the animal was entirely dissolved after the pneumogastric nerves had been divided; and he adds that, when a portion of this blood is injected into the jugular vein of another horse, a gangrenous affection is produced (§ 92.) But these effects are comparatively slow; for, in order that they may take place, the division of these nerves must previously affect the ganglia and plexi supplying the lungs and heart, and with which they are in intimate connection. When, however, these ganglia are immediately impressed, the effect is much more rapid. Such impression cannot, however, be readily made upon the ganglia themselves, owing to the protection their situation affords them from experiments of a conclusive kind. But as we find that agents, which do not affect the system when applied to the voluntary nerves, or the brain itself, will act rapidly when brought in contact with parts which are especially provided with the other class of nerves, and manifest the effects of this mode of operation upon the parts more immediately influenced from this source, we must necessarily conclude that the morbid impression of poisonous substances is primarily excited upon the latter, and not upon the former; and hence the rapidity of their effects upon the blood, — effects which are productive, no doubt, of most important consequences throughout the economy, which I am endeavouring to estimate fully and fairly, but which should not altogether obscure our perception of earlier changes, which alone can account for all the phenomena. A severe blow over the cœliac ganglion will produce instant death, and the blood will remain dissolved, and exhibit the same appearance as after death by lightning and the most virulent poisons. Here we can attribute these remarkable changes only to the sudden concussion, and annihilation of the influence exerted by this important part of the organic or ganglial class of nerves — by this central source of vital power — upon the vascular system, and to the effect thereby produced upon the blood.

141. Seeing, therefore, that the organic or ganglial nerves are chiefly distributed to the very internal membrane of the blood-vessels for the purpose of transmitting their vital influence to the blood itself, it must be inferred that, although various substances or poisons may seem to act more particularly and immediately upon the blood, and others more directly on this class of nerves according as they are applied within or without the vessels, the action cannot be restricted to either; for whatever changes the state of the one, must affect the other. That poisons, when introduced into the blood, will have an almost instantaneous effect, but not in the manner usually explained, may be readily granted and accounted for. The views upon the subject frequently stated by the Author in the Medical Repository, and in his Physiological Notes, seem more in accordance with the resulting phenomena; and are moreover confirmed by experiments and observations recently made by others; for when the poison has been applied to the cerebro-spinal nerves, it has been found by ORFILA, FONTANA, and others, to have no further operation, or even less, than when applied to other tissues, because

it is not directed to that particular organisation, upon which the functions of life more immediately depend. But when injected into the blood, it is applied to the terminations of the organic nerves in the blood-vessels — to that particular quarter where the life of the tissues and of the blood is either generated or supplied, — to the seat where the influence of these nerves affects, even if it does not vitalise, the circulating fluid, and the operation is instant and most manifest. The reader, who, possessing an intimate acquaintance with the healthy relations of the organic nerves to the blood-vessels on the one hand, and to the cerebro-spinal system on the other, examines the numerous experiments which have been performed, — by one class of experimenters to show the action of poisons upon the nerves, confounding, as all have done, the ganglial with the cerebro-spinal nerves, — and by another class to demonstrate the operation of these substances on the blood solely, both sides leaving reciprocity of action, or rather the rapid change occasioned by one system on the other, too much out of the question; and is able to detect the fallacies with which they nearly all more or less abound, chiefly from confounding distinct functions, and even different systems, with one another; will entertain but few doubts that the influence of various poisons, although more manifestly indicated in the blood, is chiefly exerted upon the nerves which terminate in the blood-vessels; and that the alterations in the contents of the vessels arise principally from previous changes produced upon these nerves, however rapid the succession of the phenomena may be.

142. The celebrated and accurate experiments made by FONTANA on the venom of the viper and the cicutas can be justly estimated only in accordance with this view; for when these substances were applied to the cerebro-spinal nerves no more rapid effect was produced by them than upon any other tissue: but, when injected into the veins, a fatal result was almost instantaneous; the blood, in the words of this able experimenter, being suddenly changed to a livid black, and soon afterwards coagulated in the lungs, heart, auricles, and liver, as well as in the large veins, with violent disease of the structure of the lungs. Now, as these substances, when added to blood as it is drawn from a vein, preserve its fluidity, they must produce, on the organic nerves ramified to the blood-vessels, a most intense effect; the alteration in the blood resulting evidently from antecedent change in the vital influence of these nerves, since no such alteration is occasioned by them when added, even much more abundantly, to blood as it flows from a vein. And there can be no doubt that virulent poisons introduced into, or having access to, blood contained in the vessels of a living animal, however the vessels may be insulated from surrounding nerves, must come in contact with its interior, and thus have an occasion given them to act upon the independent class of nerves which is especially devoted to the blood-vessels. That the very instant and intense effects which I have, in three instances, seen produced upon the blood of the human subject from the bites of serpents, and which have been minutely described by ORFILA, FONTANA, and many others, cannot arise from the diffusion of the poison in the blood, must be evident from the rapidity with which they occur, but

from the morbid impression made by them upon the vital or ganglial nerves, and instantly propagated throughout the frame; the effects of this impression first appearing as a manifest lesion in the part where the injury was inflicted, and in the blood, which, as a part of the vascular system, is co-ordinately affected with the class of nerves supplying both it and the vessels which contain it, with vital influence. From the mode of operation, therefore, of all the most virulent poisons, as hydrocyanic acid, the venom of the viper, ticunas, &c., I infer that, as the organic system of nerves may be intensely affected, without altering the state of the brain more than that of any other important organ, and then secondarily merely, so may those poisons destroy life by their effects upon this system of nerves primarily and chiefly, other lesions being consecutive, amongst which the alteration of the blood is the next most immediate, and the next most important in its relations and consequences. (See POISONS.)

143. E. *The passage into the blood of morbid matters formed in the same body that is the seat of disease*, has been particularly noticed in the articles on *Absorption and Inflammation of Veins*, I have shown, when treating on these subjects, as well as of certain organic and malignant diseases, that vitiation of the blood, and ultimately of the soft solids, more or less, is a very frequent occurrence; that it is hastened or promoted by depression of the vital energies; and that this fact, as well as the vitiation of the blood, should be taken into account in treating these maladies, particularly in their more advanced stages. It is probable that morbid matters may sometimes exist in the blood without very materially affecting its condition; but they much more frequently occasion very important changes in its constitution, as must appear from what has been stated, particularly when the powers of life begin to languish. Pus has been often detected in the veins which convey blood from parts undergoing the suppurative process, both by the older physicians and by recent writers, particularly BICHAT, FIZEAU, VELPEAU, ROCHOUX, GENDRIN, ANDRAL, DANCE, BRESCHET, and RIBES; and it seems very probable that, when thus absorbed, and not mixed with, or eliminated from, the circulation, it gives rise to various changes of the blood in the vessels, not only from attracting the fibrous corpuscles in the manner already noticed (§ 85.), but also from combining with albuminous or other constituents of this fluid. I further believe that the sanies which flows from chronic ulcers, or from the inside of veins when affected with spreading inflammation of their internal surface (see VEINS), and from the internal surface of the uterus in certain states of puerperal disease; and that the tubercular and encephaloid matter which often forms in internal viscera; may all be carried into, and most sensibly affect, the circulating fluid, and, through it, all the functions and structures of the body.

144. M. ANDRAL states, that he has often found in the blood-vessels, instead of blood, a curdy friable matter, of a dirty grey colour, and resembling either the semi-concrete pus of chronic abscesses, or the sanies of malignant ulcers, or encephaloid matter broken down and mixed with blood; and similar instances are recorded by BICHAT, BÉCLARD, and VELPEAU. In all these

cases, abscesses, tubercles, or other morbid formations, also existed in some parts of the body. (See arts. ABSORPTION, ABSCESS, &c.) In many of such cases, it is difficult to determine what may have been the state of the general mass of blood in the latter stages of the disease, owing to the period which had elapsed from the dissolution of the patient to the examination; but it is very probable that the morbid matter found in the vessels had materially affected, either directly or mediately through the organic nerves, the constitution of the whole fluids and soft solids of the body.

145. iv. PHENOMENA MATERIALLY DEPENDING UPON A VITIATED STATE OF THE BLOOD, AND SERVING TO INDICATE ITS EXISTENCE. — I have contended that the functions of depuration are very frequently concerned in occasioning, as well as in removing, a morbid condition of the circulating fluid. These functions will, therefore, evidently present some modification, when performing this latter purpose, inasmuch as the state of the blood, and of the impurities requiring change and elimination, will excite in them, as well as throughout the soft solids, more or less disturbance. In the slighter cases, the disorder of function will be less apparent; but even in these, and still more remarkably in the more severe cases, the particular function most disturbed will generally evince some relation to the kind of change existing in the blood. This relation of the change or impurity of the blood to the functions of the viscera is very similar to the mode of operation and effects of very many medicinal substances, which, having been carried into the circulation by the function of absorption, act upon particular organs according to the circumstance of their exciting or otherwise changing the vital condition of these organs while they are being circulated through or eliminated by them.

146. As respects, however, this relation of the pathological states of the blood, much requires to be ascertained, or rather but little is yet known beyond a few facts evincing that such relation sometimes actually exists. Thus we observe that excess of carbonaceous elements in the blood is removed chiefly by means of the liver, occasioning an abundant and vitiated secretion of bile. We may frequently remark, that an imperfectly elaborated chyle, or the partial absorption of sordes from the intestinal canal, renders the breath fœtid, and the urine loaded, or otherwise changed; that accumulation of the materials usually eliminated by the kidneys produces copious urinous perspirations, and the exhalation of a copious fœtid halitus from the lungs; and that putrid vegetable and animal matters, or morbid secretions carried into the circulation, derange the digestive mucous surface and secreting organs in a somewhat greater degree than other parts.

147. A. It obviously becomes most important to inquire if the phenomena resulting from change in the blood slowly brought about, or proceeding from pre-existing disease of important functions, are different from, or are nearly the same as, those which arise from the introduction of putrid or morbid matters directly into the circulation. We observe in the last stages of malignant diseases, when the blood undoubtedly becomes changed, that all the secretions are remarkably offensive, acrid, and even excoiating. The breath, per-

spiration, urine, and stools, are foetid; and the surfaces and parts with which the secretions and excretions come in contact, experience more or less change in their vital actions, and are disposed to undergo rapid disorganisation. All the circulating and secreted fluids have acquired septic and irritating properties; and discharges of sanguineous, or black, grumous, fluid matters sometimes take place from the digestive canal. The whole soft solids also lose their vital cohesion and tonic contractility, and are rapidly destroyed upon accidental injury and pressure. Hence the frequency and severity of the excoriations, ulcers, and sphacelating sores, which affect the prominent parts, sustaining the weight of the body in bed; and to this cause, in some measure, are to be imputed the ill effects sometimes following the use of blisters in the last stages of adynamic diseases. The whole surface of the body and countenance also presents more or less of the characters which distinguish change of the other structures from this all pervading cause; they lose their vital and animated hue, and become lurid, murky, or of a dirty pale tint; in some cases of a dirty or muddy pale yellow; in others slightly livid, or even altogether purplish; and in many instances, besides assuming a lurid and unhealthy colour, they are dotted with petechiæ, ecchymoses, and blotches of various shades, from a reddish tint to a reddish brown and deep purple. In numerous cases, particularly in the last stages of yellow fever, the skin is of different shades of yellow, frequently disposed in large patches, some of which are deeper than others, but the whole surface being more or less changed from its healthy tint. All these appearances arise from the state of the colourless parts of the blood, transmitted by the minute vessels of the integuments; and the admission, where ecchymosis, &c. occur, of colouring matter into vessels which did not circulate red blood in health, and the extravasation or escape of minute portions of a reddish serum, or attenuated or semi-dissolved blood, from the pores or extremities of the capillaries of the *rete mucosum*, — a change, however, which is not limited to the teguments, but which often exists still more remarkably in the mucous and submucous surfaces, and parenchymatous organs (§ 149.)

148. *B.* The rapid or direct introduction of vegetable or animal putrid matter, purulent sanies, or animal poisons, into the circulation, generally occasions, not only changes in the blood, destroying its property of coagulating, and imparting to it a tendency to quick decomposition, but also most intense disease of the principal organs: — *a.* The nervous centres are remarkably impressed, giving rise to great prostration of strength, delirium, convulsions or death, according to the intensity of the cause: — *b.* The digestive organs are affected by vomiting of morbid, brown, grumous, or other fluids: with purging of sanguineous, dark, putrid, or black matters; or distended with foetid gaseous secretions: — *c.* The respiratory and circulating functions are remarkably deranged — the respiration is quick, difficult, or panting; the action of the heart quick, weak, or fluttering, and the impulse deficient; and the pulse, at first full, open, broad, and unusually soft and compressible, soon becomes uncommonly quick, weak, and ultimately small,

thready, or fluttering: — *d.* General disease of all the functions and soft solids, accompanied with speedy death when the cause is intense; but with the symptoms of adynamic, typhoid, or putrid fever, when acting more slowly, or to a less extent, and occasioning sphacelation or gangrene of various parts, gaseous exhalations, or secretions, and various serous, sanguineous, or sanious exhalations and infiltrations.

149. *C.* The effects upon the fluids and soft solids have been already mentioned incidentally, and may, indeed, be inferred from what has been stated. These chiefly consist: — *a.* Of a foetid, decomposed, remarkably morbid, acrid, and dark or unnatural colour of all the secreted fluids: — *b.* Of diminished cohesion of the tissues generally, but most remarkably of the mucous, cellular, muscular, and glandular parts, — the heart is soft and flaccid, the blood dissolved, and the internal surface of the heart and blood-vessels tinged of a more or less deep red colour, owing, as M. TROUSSEAU has fully proved, to the altered state of the blood; the muscles are easily torn, the mucous and cellular tissues are soft and pulpy; all the structures have lost their vital and physical elasticity, and they all undergo decomposition more rapidly than usual: — *c.* Congestions, infiltrations, extravasation, &c. of fluid dark blood, into the parenchyma of the lungs, liver, kidneys, and into the cellular, mucous, muscular, and other parts, with gangrenous spots, and a foetid odour.

150. Such are the consequences of putrid or morbid matters conveyed into the circulation, and the result, in respect both of the phenomena, and of the remote organic lesions, of changes produced by these matters in the constitution of the whole fluids and structures of the body. When these matters are in a less concentrated state, or enter the circulation in a more gradual manner, they will then act in a relatively slower and less intense form, and their effects will more nearly approach those described as consequent upon a diseased state of the blood in malignant fevers (§§ 125—130.) Yet their operation will still retain nearly the same distinctive characters, the symptoms varying chiefly in degree, but not materially in kind, unless the nature of the cause has also varied. Whether we contemplate, therefore, the character and progress of the phenomena following infection of the blood from these various sources, or the nature of the lesions which ultimately result, we shall be equally struck by the marked similarity existing between them.

151. That the blood is changed in various other maladies, although to a much less extent, may be inferred from the phenomena which are observed either essentially or contingently in their course. The secondary fever in small pox is apparently connected with the partial absorption of the more fluid parts of the matter contained in the pustules, and the change thereby produced on the blood, and through it upon the economy. Instances have come before me, where, upon the rapid disappearance of the small pox eruption, purulent matter was secreted suddenly and in large quantity in the capsules of the joints, and without any previous or coexistent inflammation of these parts. In such cases, the purulent matter had evidently passed through the current of the circulation. (See ABSCESS — *Consecutive*, and ABSORPTION.) Similar occurrences are not in-

frequent in cases of inflammation of veins, and in puerperal metritis. (See VEINS, &c.)

152. *V. THERAPEUTICAL INDICATIONS AND MEASURES IN DISEASED STATES OF THE BLOOD.*—The facts and observations now adduced in illustration of the *pathology of the blood* must appear sufficient to attract greater attention to the state of this fluid in the treatment of diseases, than has been directed to it in modern times. However scanty well ascertained facts connected with this subject may seem, they are at least sufficient to justify us in directing our means of cure to the removal of those changes which may be presumed to exist in this fluid. This indication is the more safely entertained, as those means are often at the same time the most efficacious in removing pre-existing or concomitant disorder of the nervous or other systems of the frame. And it should not be overlooked, in our anticipations of the benefit resulting from curative indications founded on these views, that the most certainly beneficial means of prevention and cure of a most dangerous disease admitted to depend chiefly on the blood, viz. scurvy, is a remedy which acts principally on this fluid,—the citric acid.

153. There are certain facts, which a review of the foregoing observations will lead us to entertain as useful data for our guide, both in the recognition of changes in the blood, and in devising means for their treatment. It will be apparent from what has been adduced, that remarkable diminution or exhaustion of the vital manifestations of the organic nerves, or of the vital energy generally, renders the blood dark coloured, prevents its fibrinous particles from adhering into a coagulum when removed from the vessels, disposes the colouring matter to separate from their central corpuscles, and occasions a diminution of its saline ingredients. The effects of various matters, vegetable, animal, and mineral, when gradually and circuitously conveyed, or directly introduced, into the blood, have been particularly described, not merely as evidence of the very important changes produced by them on this fluid, but also as furnishing indications for the removal of similar alterations, when they are the results, immediate or remote, of disease actions.

154. *A. Treatment of blood abounding with fibrinous and albuminous constituents—of buffy blood, &c.*—In various diseases, particularly those which are inflammatory, in the early stages of the exanthemata, especially in certain epidemic occurrences of these maladies, the blood abounds in these constituents; and hence partly the copious albuminous and fibro-albuminous exudations which are thrown out by the blood-vessels in their progress. The knowledge which we have already obtained as to the effects of certain substances on the blood, indicates the propriety of having recourse to such as possess the property of diluting and attenuating these constituents, at the same time that they diminish the vascular action which is instrumental in secreting them; and experience fully proves, by its success, the propriety of the treatment. Blood-letting, and afterwards the free use of diluents holding in solution the alkaline carbonates and salts, more particularly the citrates of potash and magnesia, cream of tartar and borax, or the potassio-tartrate of antimony, digitalis, large doses of calomel, or other substances which have been shown to produce an

attenuating effect upon the blood, are especially indicated. Blood-letting in those cases is of the utmost service, as it diminishes general action, and removes a portion of the fibrine and albumen, which are replaced by the thinner fluids absorbed from the *prima via* and tissues.

155. *B. Treatment of blood with a loose coagulum, &c.*—Rapid coagulation and deficient adhesion of the clot have been shown to arise from weak nervous influence and vascular action; and indicate the propriety of having recourse to stimulating tonics, particularly when the smallness of the coagulum, and whey-like, milky, or turbid state of the serum, evince a poor and imperfectly elaborated blood. In this case, chalybeates, the sulphate of quinine, and the more permanent tonics, with the mineral acids, and the metallic salts, are especially required. When in addition to this state, the blood is of a very dark colour, the combination of stimulants with tonics and the alkaline salts, especially the chlorides of potassium or sodium, will be found most advantageous. In cases of this description, however, the preparations of ammonia, excepting the hydrochlorate and acetate of ammonia, although stimulating, will not be found so serviceable as other saline preparations. When, however, the hydrochlorate and acetate of ammonia are combined with excess of acid, the use of them will be advantageous. Camphor, serpentry, and arnica, the essential oils, the turpentine and balsams, are all beneficial in this state of the circulating fluid.

156. *C. The treatment in other morbid states of the blood* will necessarily vary according to the particular appearances it may present—a. When the blood coagulates imperfectly, is dark coloured, is readily decomposed, or is thin and dissolved, as in scurvy and various malignant and adynamic diseases, especially when the vital cohesion of the tissues is also impaired, the use of most of the remedies recommended above (§ 155.), particularly the chlorides, the preparations of bark, antiseptic wines, the oil of turpentine, camphor, the chloric and hydrochloric acids, with vegetable tonics, the nitro-hydrochloric acid, vinegar, citric acid, &c. The influence of acids in restoring the state of the blood, particularly when morbidly attenuated, and deficient in fibrine, appears to have been well known to the ancients, and the indications thereby offered put in practice by them. Vinegar was adopted by the Carthaginians and Romans in all their campaigns as the chief beverage, as may be gathered from VIRGIL, MARTIAL, PLINY, GALEN, &c.; and its advantages have been adverted to in modern times by LINNÆUS. There cannot be a doubt that both it and citric acid are particularly serviceable in preventing the attenuation, and tendency to dissolution, of the blood, generated, as has been shown, by excessive fatigue and exertion,—causes which have often been proved (§ 134.) powerfully to concur with unwholesome food, and vegeto-animal miasms, in the production of scurvy, dysentery, and typhoid fevers. It appears that the scurvy, which was found so destructive in Admiral Anson's fleet, was in no small degree promoted by the excessive labour of the men at the pumps,—a species of exertion which tends more than any other to accelerate the circulation, and exhaust nervous power, and consequently to produce a dissolved and incoagulable state of the blood, and to dimi-

nish its fibrine. When, however, the blood is morbidly thick and carbonaceous, when the respiratory functions are imperfectly performed, and when there appears to be a deficiency of saline constituents in the blood, as in the advanced stages of fevers, the fixed alkaline salts, and chlorides, are much to be preferred to acids.

157. *b.* Since the general neglect into which the humoral pathology has fallen, *antiseptics* have almost been discarded from practice; at least, medicines have seldom or never been given with an intention of preventing a tendency in the fluids and solids to dis-solution. It must have been long known to every person who considered attentively the operation of remedies on the frame, that many of them, either directly or indirectly, produce this effect, in conjunction with other operations; and that they act in this manner, 1st, by exciting the organic nerves, and increasing the vital cohesion of the tissues, to which they are immediately applied; and, 2dly, by their passage, to a greater or less extent, into the circulation, and operation on the blood itself, and, through its medium, on the nerves supplying the vascular system, and on the structures generally,—the antiseptic effect being the sum of those actions. Amongst the various antiseptic remedies with which we are acquainted, there is none more energetic than the chlorides or chlorurets, the spirits of turpentine, camphor, the barks, mineral and vegetable acids, the spices and aromatics, metallic, earthy, and alkaline salts, spirits, and balsams; and observation has proved to us that these are actually the means which, when appropriately employed, are most successful in removing morbid states of the blood, secretions and solids. NEEDHAM and PAULET found salt most successful in combating an epizooty characterised by a morbid state of the blood; and I had an opportunity of ascertaining that, without a necessary supply of this substance, the natives of the more insalubrious districts in intertropical Africa are carried off in great numbers by a putrid and liguiscient dysentery, for which salt, lime-juice, and cayenne pepper are their principal means of cure. It should, however, be remembered, that all stimulants are not also antiseptic in their operation on the blood. The preparations of ammonia have even an opposite effect, except the hydrochlorate combined with an excess of acid.

158. *c.* During the treatment of all diseases in which the blood becomes more or less changed, it will be requisite to have strict reference to the causes from which the change has arisen. Unwholesome food, vegeto-animal miasms, imperfect secretion and depuration, and deficient nervous and vital power, have been shown to be the chief of these. That the first and second of these should be avoided, need not be stated; and that the secreting and eliminating functions ought to be promoted, in order to purify the blood, is equally manifest. The nervous and vital energies must be not only supported, but also promoted and excited, in order that the power of secretion may be afforded to the torpid and weakened viscera; and that the crisis and vital condition of the blood may be thereby restored, and the tonicity of the capillaries, and of the tissues generally, be increased. In addition to these, also, morbid secretions should be frequently evacuated, in order that vital power may not be further reduced by

their morbid impression on the nerves and mucous digestive surface, and that the possibility of the absorption of any part of them into the circulation may be thereby avoided. But, in carrying this indication into execution, care ought to be had as to the measures which we employ. Gentle means are generally requisite, as rhubarb, &c. But those substances, which, with an aperient operation, possess also a stimulating and antiseptic operation, as the oil of turpentine, should be selected; or, if other substances be preferred, they should be combined with tonics, antiseptics, and stimulants. Formulæ 266, 437, 572, in the *Appendix*, are good examples of this combination.

159. *d.* In all the alterations of the blood resulting from the introduction or absorption of morbid matters from parts previously diseased, whatever tends to lower nervous and vital power, or to promote absorption—more particularly blood-letting, which operates in both these ways—ought to be guarded against, and a diametrically opposite plan of cure adopted; not neglecting at the same time the promotion of the depurative and excreting functions.

160. *e.* In diseases where it seems evident that the watery and saline parts of the blood are drained off, by the continued exudations from the mucous surfaces, as in cholera, particularly epidemic cholera, diarrhœa and dysentery attended by dangerous symptoms, much advantage might accrue from the injection of warm water into the veins, holding a very small proportion of saline matter, particularly the chloride of sodium and carbonate of soda, with a minute quantity of some mild stimulant and astringent, in solution; care being taken that the latter ingredient be not in nearly such quantity as to effect the albumen of the blood. Spirit of wine, ammonia, sulphate of quinine, &c. may be thus employed. (See *Poisons*, for *treatment of Poisoning of the Blood*.)

161. *D. Prophylaxis, or the prevention of morbid states of the blood.*—The extended inquiry which has been entered into respecting the causes of the alterations which take place in the blood, furnish the chief indications for preventing their occurrence. The primary influence of the organic nerves upon the blood, and the effect rapidly produced upon this fluid by a diminution or vitiation of this influence, having been conclusively shown in respect of changes directly produced by this class of nerves, both on the blood circulating in the vessels, and on the functions of secretion and depuration, it becomes a matter of the first moment to preserve the vital manifestations of this important part of the nervous system from experiencing depression or exhaustion; especially where causes having this effect are in operation, and where there is any risk of those morbid matters, which have been shown in this article to be the chief sources of vitiation, being carried into the blood; particularly those vegeto-animal, or animal effluvia, which, floating in a moist atmosphere, act both by depressing these vital manifestations, and by infecting the blood itself. Persons exposed to those sources of disease should live on a due proportion of farinaceous and other vegetable substances, with a moderate proportion of fresh animal food, and preserve the energies of the digestive and assimilating organs: always attentively promoting the functions of secretion, depuration, and excre-

tion. At the same time many of the substances mentioned above may be employed as beverages, condiments, or preventives; more particularly the medicines formerly denominated antiscorbutics, the citric acid, lemons, lemon-juice with sugar; spruce beer, vinegar in which the warm spices, as capsicums, have been infused; the chlorides, camphor, quinine, &c. As it has been satisfactorily shown that great excitement and acceleration of the circulation, besides exhausting nervous and vital power, have also the effect of changing and even of corrupting, the state of the blood, such excitement should be prevented, and allayed when present, by appropriate evacuations, and by refrigerant saline medicines and beverages.

CLASSIF. 3. Class, Sanguineous Function; 4. Order, Cachexies (Good). IV. CLASS, II. ORDER (Author, see Preface).

1. DEFIN. A blue violet, or purple, colour of the integuments, particularly of parts usually presenting a rose or flesh tint, as the cheeks, lips, mucous surfaces, &c.

2. A blue or purple colour of the integuments of parts, or nearly the whole of the body, may occur as a symptom in the last stage of various acute diseases. But it is present from the beginning of this affection, is frequently connected with comparatively little disturbance until some sudden change takes place, and generally results from chronic organic lesion. In other maladies this colour is an accidental, occasional, and not the most important symptom; in this affection it appears as the only, or the most remarkable, change observed during life.

3. I. ITS PATHOLOGY.—According to M. GINTRAC, who has directed much attention to this affection, it always proceeds from organic change of the heart or large vessels; the admixture of venous with arterial blood, and the distribution of it to the surfaces of the body, being the immediate or essential cause of the alteration of colour. This pathology agrees with the opinion of SENAC and MORGAGNI: it has, however, been disputed. M. CORVISART first threw out doubts of the constant origin of cyanosis in this source; and more recently MM. FERRUS, BRESCHET, MARC, LOUIS, FOUQUIER, and CRAMPTON, have adduced facts which seem to militate against it, while it has received the able support of M. BOULLAUD.

4. M. FERRUS contends, 1st, That cyanosis sometimes has existed to an intense degree, and yet upon *post mortem* examination no lesion could be detected admitting of the admixture of venous blood; nor any organic change of the heart or respiratory organs: 2d, That the opening of Botal may continue unclosed for many years without blueness of the surface being occasioned: and, 3d, That the admixture and circulation of venous with arterial blood have been demonstrated to occur in some cases, without giving rise to this peculiar appearance. That the second and third objections are well founded seems almost incontrovertible. Numerous instances have been recorded by LOUIS, and others, which fully prove these facts. I have met with cases in children, where the communication between both sides of the heart seemed very free, and yet no alteration of the natural colour existed: and others, in which the change was evident during the paroxysms of suffocation only. But I must agree with CORVISART, RICHERAND, CLOQUET, GINTRAC, and BOULLAUD, that the existence of this opening is no certain proof of admixture of the venous and arterial blood; for if the contractile powers of both ventricles are nearly equal, in relation to the resistance to be overcome, and if the natural openings of the cavities be not obstructed, no admixture of the blood in both sides of the heart could take place.

5. The principal force of the objections, therefore, urged by M. FERRUS, evidently rests upon the fact of the non-existence of organic diseases of the heart, large vessels, or lungs, in some cases of the disease,—a fact which is still not satis-

BLUE DISEASE. SYN. *Cyanosis* (κύανος, blue, and νόσος, disease), *Beaumes*, *Morbus Cæruleus*, *Cyanopathia*, Marc. *Eaangia Cy-*

factorily established. I believe that it may be safely concluded, that the blue disease of infants and children is very generally dependent upon a communication between the opposite sides of the heart, or some malformation of the heart or large arteries, particularly contraction of the origin of the pulmonary artery, or some other change affecting the circulation through the right cavities of the organ; whilst in older and aged persons, a similar colour of the surface may proceed from whatever obstructs the circulation through the large veins, lungs, or heart, and even from simple congestion of the venous capillaries from loss of vital power; and in these latter cases the affection more nearly approaches the blueness observed to occur as a dangerous symptom of various acute diseases of the lungs and heart, as of asphyxy, and of pestilential cholera.

6. i. *Symptoms, progress, and terminations of blue disease.*—The bluish tint of the external surfaces, whence this malady derives its name, is not equally deep in every part. It is usually deepest over the whole of the face, and the lips in particular, on the hands, feet, and genitals. During any effort, or when crying, this symptom is much more marked than during repose: at the same time the parts presenting a bluish colour, or a violet of the darkest shade, are more or less puffed. The circulating and respiratory functions are rarely without derangement. The disordered circulation is characterised by palpitations more or less violent; sometimes accompanied by a very distinct bellows sound, and by a purring tremor, tendency to fainting, and serious effusions. The breathing is laboured and panting after the slightest effort. The warmth of the body is considerably diminished, and patients are very sensible of cold. The functions in general, and principally those of locomotion, are more or less languid, and, as it were, benumbed.

7. The symptoms just described do not always exist in the same degree, during the continuation of the malady. It may even be said that the disorder is made up of a succession of paroxysms and remissions. In the paroxysms alone we observe these frequent faintings, that tumultuous palpitation of the heart, and suffocations, which endanger the life of the patient. No rule can be relied on as to the recurrence of these paroxysms; in fact, if it be certain that they are often brought on by over-exertion, fatigue, and violent mental agitation, it is equally certain that they occur without any assignable cause, and are more frequent in winter than in summer. The length of the paroxysm varies: it sometimes lasts several hours, and generally abates gradually. The termination of cyanosis is fatal to most patients; but some appear to recover entirely; others live for many years. Cases of this kind have been recorded by MORGAGNE, SANDIFORT, and RICHERAND. The death caused by this disorder is sometimes very sudden; but in the majority of cases it is preceded by an intense suffering, characterised by the most acute anguish, difficulty of breathing, fainting fits, and cold sweats. In a case of remarkable blueness from birth, in a girl, who was for some time under my care, the colour changed in the course of two or three years, to a dirty yellowish, chlorotic tint, which is still retained up to the thirteenth year. The disorder of the heart's action and respiration, in this case,

although more or less considerable, was never very severe; but the child was always remarkably delicate, and incapable of any bodily or mental exercise.

8. ii. *Lesions observed after death: and their connection with the symptoms.*—1st, The most common lesion is the persistence or the re-establishment of the opening of Botal. This communication of the two auricles is generally accompanied by an obstacle to the passage of the blood from the right auricle into the corresponding ventricle, or from the latter into the pulmonary artery. Twenty-seven cases out of fifty-three reported by M. GINTRAC, presented such an obstacle. In twenty-six of these cases the circulation on the right side of the heart was impeded either by a contraction or by a total obliteration of the orifice of the pulmonary artery, and in only one case by the contraction of the right auriculo-ventricular orifice. Co-existent with these lesions is usually a hypertrophy of the right ventricle and auricle, or of one only of these cavities, with or without dilatation. Sometimes the ventricular cavity is itself contracted. 2dly, The ventricular partition has often presented a solution of continuity of more or less extent. 3dly, The arterial canal remained open in some subjects. 4thly, In one of the cases reported by M. GINTRAC, the two auricles (imperfectly divided) opened into the right ventricle: the latter being very large, communicated freely with the left, which (narrow and without auricular orifice) gave origin to the aorta. 5thly, In another case, the aorta and pulmonary artery sprung from the left ventricle, the right being almost obliterated, and the inter-auricular partition perforated. 6thly, In another instance, the opening of Botal was preserved; the aorta disappeared after having supplied the cephalic and brachial trunks; the pulmonary artery, receiving the blood from both ventricles, formed the descending aorta. 7thly, Such a transposition of the larger arterial trunks has been witnessed, as the aorta springing from the right ventricle, and the pulmonary artery from the left; the opening of Botal and the arterial canal still remaining, or only the latter. 8thly, In some cases the heart consisted only of one auricle and one ventricle. 9thly, Two superior venæ cavae were seen, the one opening into the left auricle. It is unnecessary here to enlarge upon the other lesions noticed in persons afflicted with this complaint, because they do not necessarily belong to the subject.

9. iii. As respects the relation between the symptoms and lesions, M. BOUILLAUD remarks, that the alterations pointed out in the central organs of circulation have usually the effect of permitting the black blood to mingle with the red; but some of these lesions, as previously observed, such as the opening of Botal, do not necessarily entail this admixture; for which reason they are not invariably accompanied by blueness of the integuments; either the black blood not having mingled with the red, or the mixture being insufficient to produce the bluish colour. But when the arterial canal remains upon; when the aorta springs from both ventricles jointly; or when, to the communication between the right and left cavities, is superadded an obstacle to the free current of blood in the former; a considerable quantity of black blood must necessarily mix with the red.

Whenever an abnormal communication between the cavities of the right and left divisions of the heart co-exists with an obstacle to the circulation of the blood in the right ventricle or in the pulmonary artery, the mixture of the blood is not the sole cause of the discolouration of the skin, the puffing of certain parts, of various serous congestions, &c. In fact, it is evident, that the impeded circulation contributes mainly to the production of these phenomena. Should we not also attribute to the contraction of the auriculo-ventricular, or ventriculo-pulmonary orifices, the bellows sound and the purring tremor remarked in some patients? However this may be, some of the lesions coincident with blueness of the teguments are invariably congenital; while others (such as the communication between the right and left regions of the heart) may be either congenital or accidental.

10. iv. The causes which develop most of the congenital lesions, from which blueness may ensue, are not easily determined on. But a communication between the right and left cavities of the heart may be occasioned by ulceration of the auricular and ventricular partitions, or by the rupture of these partitions, especially of the auricular, in violent and lengthened efforts. An obstacle to the course of the blood through the right auriculo-ventricular, or the ventriculo-pulmonary orifice, may also, particularly in the early stages of life, induce an abnormal communication between the two auricles, by ungluing, as it were, the valvular laminae, which, by their agglutination, have obliterated the opening of Botal. The existence of a similar obstacle at an intra-uterine period of life, when the opening still remains, may be also deemed a sufficing cause for its ultimate non-obliteration. (*Dict. de Méd. et Chirurg. Prat. t. vi. p. 7.*)

11. I am of opinion, not only that such obstacles have very generally existed during intra-uterine life, and been the cause of the blueness observed afterwards, but that they have also occasioned, during foetal existence, a permanent state of distension; and thence, in some respects, malformation of the capillary system, particularly in the cutaneous and mucous surfaces, favouring congestion, and languid circulation through them after birth, and the consequent blueness, and the puffiness that generally attends it. I may add, as a matter of diagnosis, that very intense and general blueness is not uncommonly produced by the incautious and internal use of the nitrate of silver. I have observed two or three such cases, and others are recorded by ALBERS, ROGET, &c. (*Med. Chir. Trans. vol. vii. p. 284.*)

12. II. TREATMENT. — Art is of little avail in this malady. We must chiefly depend upon the efforts of nature in bringing gradually about a change in the lesions on which it depends; and attempt to assist her efforts, by directing bodily and mental repose, and a pure, mild, dry, equable and somewhat warm air; by attending strictly to the state of the biliary and other secretions, and the digestive functions; and by recommending gently tonic medicines, with an easily digested and nutritious diet. During the paroxysms, M. BOUILLAUD recommends blood-letting, — a practice which is by no means warranted by my experience. Depletions, and all other lowering means, aggravate the symptoms, and seldom or

never succeed in removing the severity of the paroxysms, for which he advises them. I have derived more advantage from stimulating pediluvia, frictions of the surface of the body and lower extremities, and the administration of gentle antispasmodics and stimulants. (See F. 348. 424. 663.) In one or two instances, I conceived that some advantage was derived from the preparations of iron combined with the fixed alkaline carbonates. (See also F. 94. 662. 718. 920.)

BRAIN AND MEMBRANES — DISEASES OF.
 SYN. Ἐγκέφαλος, Gr. Cerebrum, Eucephalon, Lat. Cerevau, Encéphale Fr. Das Hirn, Gehirn, Ger. Cerebro, Ital.

CLASSIF. SPECIAL PATHOLOGY AND MORBID STRUCTURES. IV. CLASS, III. ORDER
 (Author, see Preface).

I. With the view of avoiding unnecessary repetition, and of furnishing a complete account of the changes and morbid phenomena connected with the parts contained within the cranium, alterations of structure will be considered in the first place, and in systematic connection; and, afterwards, inflammations affecting either the brain, or its membranes, will receive attention. As similar lesions develop themselves in the brain, or its membranes, in the course of a variety of diseases; and as many of those which are most commonly found upon dissection give rise to very different phenomena during life; their arrangement in a separate form will facilitate reference to them, when those specific states of disease, which they either originate in, or occasion, are being discussed. Thus tumours formed in the brain, or purulent matter secreted there, or induration or softening of the cerebral substance, &c. are not infrequently found in cases of either palsy, epilepsy, insanity, or encephalitis, without limitation to any one of them. Instead, however, of describing these and various other lesions, when considering each of these diseases, I shall here give a minute description of the morbid structures observed in the brain and its membranes, and refer merely, when discussing these and other diseases implicating the cerebral functions, to those changes most commonly found on dissection of fatal cases, as they are described in this article.

2. Of all the organs of the body the BRAIN is the most exquisitely and incomprehensively formed, and presents the least intimacy of connection between the results of dissection and the phenomena of disease. The most violent symptoms referrible to this organ often exist during life; and yet, on the most careful examination, after death, either no appreciable lesion, or none sufficient to account for the phenomena, can be detected. Whilst, on the other hand, many and most important changes are frequently discovered in both the brain and its membranes, in cases which betrayed either no cerebral disorder, or none calculated to excite suspicion during life of any organic change. It is extremely important to be aware, not only of this fact, but of the cir-

cumstance just alluded to, that the same irritable appearances, or, at least, states so nearly alike that they cannot be distinguished, will frequently be found after maladies very dissimilar as regards their cause, nature, and consequences. Thus, irritation of the brain occurring in the progress of fevers, and the exanthemata; convulsions, insanity, drunkenness, puerperal derangements, metastasis of gout, and various other diseases, will be attended with congestions, injection of the blood-vessels, secretions of lymph or serum, or of air between the membranes, &c.—states in every respect similar to those proceeding from idiopathic inflammation. Nor should it be forgotten, that the kind of death, the particular circumstances attending it, and the positions and changes to which the body is subjected immediately afterwards, tend very materially to influence the appearance and states of the parts within the cranium. In the view which I am about to take of the principal lesions of structure affecting the encephalon, I shall first notice the morbid states of its membranes; next, the lesions presented by its sinuses and other blood-vessels; and, lastly, the diseased appearances of the different parts of the encephalon itself.

3. I. MORBID STATES OF THE MEMBRANES OF THE BRAIN. — The intimate connection which the membranes of the brain have with the cranial bones on the one side, and the brain itself on the other, and their expansion between both, render them extremely liable to participate in all the malformations, diseases, and external injuries of those parts. Whilst they most commonly, with the limpid fluid exuded between them, separate those parts, and facilitate the motions of the latter, they also often prevent the extension of morbid action from the one to the other. But they do not always succeed in thus limiting disease; for they frequently become secondarily affected during maladies commencing either in the skull or the brain; and, when thus involved, they, in some measure, become the medium of mutual infection. But the membranes are not only thus secondarily affected; they are also not infrequently themselves the primary seat of disease; and when such is the case, the parts on each side of them, particularly the brain, seldom fail of participating more or less in the disturbance. Thus we often find them the primary seat of congestion, and of inflammation, with their consequences, as effusion between them of various kinds of fluids; and the source whence disease has extended to the brain itself. Those changes are presented to our view, not only in the primary inflammations of the membranes, but also in several forms of fever; in morbid affections of the mind, tetanus, delirium tremens, convulsions, epilepsy, apoplexy, palsy, and other diseases, wherein we have reason to suppose that the brain itself is either primarily and principally affected, or participates largely in the morbid states of its envelopes.

4. i. The DURA MATER is often found unusually adherent to the cranium, even when the brain and its membranes have been quite free from change, but more commonly when chronic disease has existed in either the one or the other. It is also sometimes slightly adherent to the skull, and occasionally this want of adhesion is very remarkable. In some instances, the dura mater is separated entirely from a portion of the cranial bones.

In some rare instances, the space is filled with a watery fluid; but this has only been met with in hydroptic children. The separation is generally the result of external injuries; and either blood or pus, or even both, is usually found in the space between the bone and the membrane. In some cases, these effused fluids, particularly blood, either fluid or in coagula, are in considerable quantity, occasioning the usual symptoms depending upon pressure. Lymph, in various degrees of firmness, is also found between a part of the dura mater and the skull; and this, as well as pus, with which the lymph may be partially mixed, are generally the result of inflammations consequent upon external injuries. These appearances have been sometimes observed in fatal cases of epilepsy, but only when the patient has received some injury during the paroxysm. They are often connected with a puffy swelling of a corresponding portion of the scalp.

5. The dura mater itself may be here viewed as two membranes, closely united throughout by means of fine, close, cellular tissue: the exterior, or that applied to the cranial bones, resembling its structure, and performing the office of periotium; the interior, or unattached, being a reflection of the arachnoid, and having, as respects its functions, a more intimate relation to the included organs: the former being a fibrous, the latter, a serous membrane.

6. A.—a. The fibrous structure of the dura mater is frequently more than usually vascular, particularly in fatal cases of apoplexy, paralysis, fever, with cerebral symptoms, epilepsy, and in the congestions which occur in the last stages of whooping cough, pulmonary diseases, asphyxia, and poisoning by narcotics. This state is, however, very different from inflammation, as the minute capillaries do not present the same degree of redness, particularly in the unattached or arachnoid surface. This structure is sometimes tinged with bile, and of a deep yellow colour through its whole extent, as in cases of acute jaundice, which are attended with comatose symptoms. After contusions, or when suppurations exist beneath or exterior to it, it is either yellow, dusky, bluish, brownish, or even blackish. It is also occasionally spotted with black, in some cases of melanosis. In some instances, this membrane seems distended from fluids effused in the cavities of the brain, or between the membranes; in others it is apparently corrugated or collapsed. This latter state generally proceeds from it having been punctured during the separation of the calvarium, the fluid which it had contained having thereby escaped. But it is sometimes noticed where no such accident occurs, particularly in extremely emaciated bodies, or in the very aged, when little or no water is collected beneath it. A more than usual dryness and transparency is occasionally observed in this as well as in similar structures. Unusual dryness is also sometimes conjoined with a shrivelled state, and deficient transparency. Otto thinks that this is one of the remote effects of inflammation.

7. b. It is but rarely inflamed, excepting from external injuries, and then generally in circumscribed patches of greater or less size. In these cases, the injection and redness are very remarkable, particularly in the vicinity of purulent formations and injuries of the bones, or where ulceration

discoloration, fractures, abscesses, &c. exist in its vicinity. *Suppurations*, in which the pus is found between its layers, or on its outer surface, are very rare. Cases, however, are referred to by OTTO of this occurrence. When suppuration does occur, it is generally seated in its inner surface. In some of these cases, the purulent matter has eroded, and perforated the skull and layers of the dura mater exterior to it. *Thickening* of the dura mater is not an usual result of chronic states of inflammation. It varies extremely in degree, and it is sometimes so great as to occasion symptoms of pressure and irritation. It is sometimes found in fatal cases of epilepsy and paralysis; and is occasionally conjoined to *induration* of the thickened part. *Ossification* of the fibrous structure of the dura mater is a comparatively rare occurrence, whilst ossific deposits in its free or arachnoid surface are very common. In the former case, the bony matter follows the fibrous arrangement of the membrane, and involves its substance. Two interesting specimens of this change are referred to by Dr. BRIGHT (*Report of Medical Cases*, &c. vol. ii. p. 663.). Ossific deposits may likewise be ascribed to slight, or chronic states of inflammatory action.

8. *c. Tumours* also form in the dura mater. Those which are most intimately connected with it have a *fibrous* structure; whilst the *fungoid* tumours sometimes observed seem to be common to both this membrane and the arachnoid lining it. Nor are they limited to the dura mater, as supposed by LOUIS and the WENZELS; but they may arise also in the bones of the skull, as shown by WALTHER, GRAAFF, and SIEBOLD; and even in the pericranium, as contended for by OTTO, EBERMAYER, and CRUVEILHIER. *Osteosarcoma* or *fungus cranii*, therefore, as stated by VON WALTHER, and *fungus duræ matris*, are merely different, although often simultaneously occurring forms of the same disease. (See § 17.) When fungous tumours originate in the dura mater, they not infrequently perforate the skull, by occasioning absorption of the superincumbent portion of bone; but they also often involve the bone in a similar change, giving rise to *fungus cranii* as now stated. They occur in every part of the dura mater, commencing more frequently in its inner coat, and are found oftener in this situation, than in the bone itself, or the pericranium. (See CRANIUM.)

9. *d. Other kinds of tumour* are occasionally found in the dura mater. But those of a constitutional origin usually commence either in the arachnoid covering the dura mater, or in the fine connecting cellular tissue. They, however, generally soon involve, not only this latter membrane, but also occasionally the cranial bones. Of these tumours, comprising the *scrofulous*, *scirrhous*, *carcinomatous*, and the *hematoid*, I shall make more particular mention in the sequel. Although sometimes found in the inner surface of the dura mater, they are met with only consecutively upon their original manifestation in some other part of the body. More rare than any of the foregoing, is the occurrence of *fatty* and *encysted tumours* on the exterior surface, or between the layers of the dura mater. They have been found in this situation by MORGAGNI, FRICKE, and OTTO; and, in very rare instances, have been observed to contain hair. *Scrofulous* tumours are less frequently found

exteriorly to, and between the layers of, the dura mater, than in its internal surface.

10. *c. Unusual thinness* has been observed in some parts of this membrane; and some of its processes have been wanting, owing to their *absorption*; in some cases, without any obvious cause, but more frequently from the pressure of a tumour of the brain, or some other morbid enlargement. "The falciform process, and a part of the tentorium, have been wholly removed, and large portions of the dura mater and its processes have been found as thin as silver paper." (HOOPER, *Morbid Anatomy of the Brain*, &c. p. 29.) When portions of the *dura mater* are destroyed by any internal cause, or even by external injury affecting the bone, they are rarely or never reproduced, and never otherwise than by a thick or *dense cellular tissue* closely connected with the newly formed bone; or, if the bone be not produced, after having been destroyed, it assumes a fibro-cartilaginous state, and becomes consolidated into a common cicatrix with the integuments. *Rupture*, or *laceration* of the dura mater is generally the consequence of fractures of the cranium and concussion. It has, however, proceeded from violent coughing, after the superincumbent bone has been removed by fracture, or by trepanning, &c.

11. *B. Morbid states of the arachnoid covering the dura mater.*—*a.* The internal surface of the dura mater is lined by a reflected portion of the arachnoid membrane, the unattached surface of the dura mater thus consisting of a true serous membrane, intimately attached to, although different in its nature from, the fibrous structure which it covers. *Inflammation*, whether originating in the dura mater itself, or in this surface, chiefly manifests its distinctive characters and effects on this lining: and generally presents, especially in the early stages of the acute disease, a minutely injected state of the capillaries, with a bright red tinge of the whole surface. This appearance has been beautifully illustrated in the first of Dr. HOOPER's plates of lesions of the brain. When acute inflammation attacks this part, it is generally confined to one side, the longitudinal sinus or the falx furnishing the boundary of the disease. In very acute attacks, and in the advanced stages of inflammation of the dura mater, the internal surface becomes covered by a layer of *fibrous lymph*, into which, as I have shown in respect to serous membranes generally, minute vessels may be traced, when the exudation of this substance has been proceeding for some days. It is usually diaphanous, very delicate, and forming a complete adventitious membrane. In other cases, a much thicker, opaque, and albuminous-like membrane, of much firmness, less vascular and less intimately adherent to the dura mater, is formed. Although the fibrine and albuminous matter exuded may be both abundant, and thus provided with vessels, it is seldom the medium of adhesion; or, indeed, at all adherent, to the arachnoid covering the convolutions: and if adhesions have formed, they are very slight in respect of this latter duplicature of the arachnoid, unless very acute inflammation also exists in the pia mater, directly opposite to the inflamed surface of the dura mater.

12. *b.* In more chronic forms of inflammation, this surface not infrequently assumes a *spongy appearance*, with more or less redness and marked

injection of the vessels. In some cases it has a *villous aspect*, from a slight exudation of albuminous matter, and interstitial effusion of serum in the texture of the arachnoid lining. *Purulent matter* is seldom formed to any considerable extent; but, when it is secreted, it usually spreads thinly over the membrane. It seems generally to proceed from the inflamed surface, without any distinct appearance of ulceration. In some cases, however, owing to adhesions of the membranes around it, circumscribed accumulations of pus are met with; and these may cause the erosion of the dura mater and bones exterior to them. Although the productions now noticed sometimes are observed to follow idiopathic inflammations of this part, they are more frequently the results of external injuries; and are more commonly met with in the parts which cover the hemispheres, than in the basis of the skull, unless there be a very general state of inflammation of the parts within the cranium.

13. *c. Adhesions of the lining membrane of the dura mater to the arachnoid and pia mater* are chiefly observed when both reflections of the arachnoid are inflamed, particularly in chronic affections of the cranial contents. The medium of adhesion varies considerably. It is frequently found to consist of a firm but thin exudation of fibrinous lymph or of albuminous matter: in some cases, delicate, diaphanous, and vascular; in others thick, opaque, and less intimately adherent to the internal surface of the dura mater than the preceding. In a few instances it is formed of fine filamentous bands passing through a more than usually copious effusion of serum; and occasionally the membranes are intimately and firmly joined, even without any very apparent medium of union, particularly at the centre of the part adherent. This is chiefly seen immediately over or near the situation of severe organic disease of the brain itself, as abscess, tumours, superficial ulcerations, &c. In some cases, the adhesions are so firm that, in attempting to raise the dura mater, the subjacent membranes, with a portion of the brain, are removed along with it.

14. *d. Ecchymosis and purple spots* arising from the effusion of blood, in minute patches, beneath its arachnoid lining, are sometimes observed in the unattached surface of the dura mater, and partake of the character of purpura. They are most commonly found in cases of cerebral disease, which has been complicated with chronic change of the biliary organs and deficient energies of life, — or with general cachexia. *Carbonaceous deposits*, or *melanosis*, have also been sometimes observed in the situation. Dr. Bright believes them to be the result of extravasated blood. (See the art. MELANOSIS.) *Ossific deposits*, generally disposed in plates, or much thicker in the centre than the circumference, and varying much in number and situation, are also frequently found towards the surface of the dura mater. They seem covered by the arachnoid, are closely adherent to the dura mater, and formed between them. They occasionally present an irregular surface, or assume a nearly conical form, and are often connected with nervous diseases, particularly epilepsy. They are most frequently met with upon the falx, and near the part where the dura mater separates to form the longitudinal sinus.

15. *e. Tumours* not infrequently proceed from the internal surface of the dura mater. Many of

those productions are actually formed in the arachnoid lining this surface; being only adherent, and often very slightly, to the proper structure of the dura mater, and in no way changing its characters. As these tumours increase in bulk, they gradually produce debility of both mind and body, particularly the former. Much of the severity and rapidity of these effects will, however, depend upon the rapidity of their formation. When small, and sources rather of irritation than compression, convulsive affections are oftener occasioned by them than paralysis: when large, they more frequently give rise to paralysis than convulsions: but either of them may be followed by any of those affections; mental weakness being the more constant, and often the most remarkable effect. Many, also, of the tumours developed in the dura mater can scarcely be said to originate either in its fibrous membrane, or in its serous or arachnoid lining: but should rather be referred, at their commencement, to the cellular tissue uniting those layers. Amongst those which seem more frequently at least to originate in this latter situation, — although often involving, and in a very short time, all the layers of the dura mater, and even the parts adjoining, — the scrofulous, the cartilaginous, the hamatomatoid, and the encephaloid or fungous tumours, require the most particular notice.

16. *a. The scrofulous tumour* is found on the internal surface of the dura mater, having an organised, fleshy, solid, and humid appearance; and is but rarely met with, and only in connection with scrofulous disease in some other part of the body.

β. The *cartilaginous tumour* is generally seated in close connection with the dura mater, and under its arachnoid lining. It varies as much in the perfection of the cartilaginous state, as in its size. It is sometimes perfectly cartilaginous; at other times merely gristly. It is oftenest met with in the faliform process and tentorium; and is occasionally attended with ossific deposits in the same situations. Indeed, as remarked by Dr. Hooper and Dr. Monro, some of those tumours are partly ossified, so that the cartilaginous state seems to be often an intermediate state between that of gristly firmness and complete ossification. A case is described, by Mr. Watson, in Dr. Monro's work, of a cartilaginous tumour, the size of a walnut, containing bony matter towards its centre, growing from the dura mater. The *sub-cartilaginous tumours* are often tuberculous, of a dirty white colour, always distinct, but often numerous, and varying from the size of a pea to that of a hazel-nut. They generally are found between the dura mater and its arachnoid lining, have a broad base, present a clean smooth surface when divided, are firm, and devoid of vascularity. They seldom affect much the superincumbent dura mater and bone, but deeply indent the substance of the brain.

17. *γ. The malignant tumours*, which are occasionally met with in the dura mater, assume the *sarcomatous*, the *carcinomatous*, and the *fungoid* characters. The fungoid disease may be either *encephaloid*, or *hamatoid*. The *encephaloid tumour* is not common. Its divided surface is cellular and spongy, and gives out a pap-like matter when pressed. Its structure is more generally approaching to the fungoid, than to the tuberculous. It seems to be entirely produced from the

lining membrane of the dura mater, and is almost always connected with scirrhus or malignant diseases originating in some other part of the body. The *hematoid tumour* is of the colour of venous blood, has a broad base, and a fungous, sometimes a tuberculous, structure. It is soft to the touch, is covered by a delicately lamellated tissue, thinner than silver paper. When divided it appears spongy, and extremely vascular. It is very rare, and is always connected with the primary occurrence of the disease in some other part of the body.

δ. The *simple cyst*, or *watery tumour*, the *hygroma* of Dr. HOOPER, is seldom or never observed in this situation; although frequently in other parts of the encephalon. A case of it, however, occurred to Dr. DUNCAN. The *acephalocyst*, or headless hydatid, has been found connected with the arachnoid of the dura mater, in a very few cases.

18. ε. The CAUSES of malignant, or constitutional tumours in the dura mater, are generally external wounds or contusions, concussions, the scrofulous or syphilitic taint, and most commonly previously existing disease of a similar nature in other parts of the body.

19. ζ. The SYMPTOMS by which their existence may be inferred are extremely equivocal. At the early periods of their growth, they frequently give rise to little or no disturbance. Much, however, will depend upon the rapidity with which they are formed, and their situation. When they grow slowly, the portion of brain becomes gradually accustomed to, and as it were, insensible of, the pressure; it seems to waste; and if this compressed and atrophied part be not indispensable to the free exercise of the sensorial, intellectual, and locomotive functions, the disease produces no evident or sensible indication of its existence. But sooner or later the compression produced by them on the brain, or the irritation occasioned in the membranes, gives rise to effects of the most serious nature. These chiefly consist of paralysis, epileptic convulsions, and apoplexy, occasionally occurring as suddenly as in the sanguineous forms of these diseases; but frequently in a more or less gradual manner. When the tumour is situated in or near the base of the brain, the symptoms, whether those of compression or of mental disorder, generally supervene rapidly. Most commonly, however, sensation and volition gradually disappear from the limbs which correspond with the compressed portions of brain; the intellectual powers are obscured, and the patient soon becomes hemiplegic and idiotic. The gradual accessions of hemiplegia, and of the other symptoms of compression, generally indicate that the paralysis arises from the development of a tumour, rather than from the formation of an apoplectic effusion of blood. The frequent occurrence, also, of acute pain in the paralysed limbs, of epileptic movements, antecedent cephalalgia of a violent character, with obscuration of the intellectual powers, somnolency, a cachectic habit of body, or the occurrence of disease in other parts of the body calculated to taint the system, as the scrofulous, syphilitic, carcinomatous, or fungoid diseases, are also circumstances indicating the formation of tumours in the membranes of the brain.

20. These tumours usually give rise to further disease of the brain, or its membranes, before

terminating life; such as inflammation of the parts adjoining, effusions of fluid beneath or between the membranes, adhesions of their opposite surfaces, destruction of the bones, softening and pulpy destruction, &c. of the cerebral substance; sanguineous effusion in this situation: and these increase the severity of the symptoms, and hasten the fatal termination. It should, however, be kept in recollection, that the effects produced by these tumours have in general no relation to their bulk. One of the circumference of one or two inches will often occasion (the situation and nature of the tumour being the same) as violent effects as another of four or five inches. It is, moreover, not to the tumour itself that the symptoms are to be imputed, but to the effects it produces on the brain and membranes.

21. ii. MORBID CHANGES OF THE ARACHNOID AND PIA MATER. — A. The ARACHNOID is so delicate, perfectly transparent, and so intimately adherent to the pia mater, except at the base of the brain, as to admit with difficulty of separation from it. That lesions, therefore, of the latter membrane should affect also the former, cannot be a matter of surprise. Indeed, the greater number of changes which I shall have to notice in this section generally invade both these membranes simultaneously, although either of them may be affected in a more or less marked degree.

22. a. *Inflammatory action* gives rise, though very rarely, about the optic nerves and between the lobes of the cerebellum, to small patches of beautiful *vascularity* in the *arachnoid*; the surrounding portions of this membrane being opaque, and adhering to *inflamed* parts of the pia mater. It is, however, very uncommon to find, even in the most intense inflammation of these membranes, red vessels in the arachnoid. The most frequent results of inflammation in this situation are, *thickening*, and the effusion of a watery or *serous fluid* under it, raising and separating it, in places, from the pia mater, particularly in the intergyral spaces. The *fluid* secreted in this situation is generally transparent, but it is sometimes turbid and albuminous, occasionally opaque, and tinged with bile in jaundice. In rarer cases it is tinged with blood. *Thickening*, and *opacity* of the arachnoid vary much in degree. They are occasionally so great as to obscure the vessels and membrane underneath it. Less frequent than the foregoing is the secretion of a *puriform matter*, under the opaque and thickened membrane, giving the appearance of a diffused suppuration; and still more rare is the deposit of *fibrinous lymph* unless in a state nearly approaching to an albuminous substance, or a puriform fluid.

23. b. The effusion of a *serous fluid*, in excessive quantity, exterior to the arachnoid of the pia mater, and in the bag of the arachnoid coat, around the encephalon, forming *dropsy* of the cerebral membranes, is sometimes observed. It has been fully demonstrated by M. MAGENDIE, and confirmed by other inquirers, that this membrane secretes a fluid in health, varying somewhat in quantity with the state of the brain, and of its circulation; that this fluid cannot be materially diminished, or entirely deficient, without morbid phenomena being produced; and that it may, in disease, not only be secreted in too large

quantity, but also in modified quality. In some cases of chronic and congenital hydrocephalus, particularly when accompanied with *spina bifida*, the effusion is chiefly in this situation. In those, it is usually pellucid, and the arachnoid is not materially changed in its appearance. In more rare cases, however, this fluid has been observed somewhat turbid, as well as excessive in quantity; and the arachnoid opaque and thickened. In these, it would seem to have proceeded from increased vascular action affecting this membrane and the pia mater. Effusion of a watery fluid, however, in this situation, is much less frequent than in the ventricles. It is commonly congenital and chronic in these latter cases; and it sometimes protrudes the membranes, in large watery tumours, through apertures in, or between, the bones of the head. Several cases of this kind have occurred to me in the Infirmary for Children. In dropsy of the ventricles, which is most common, producing almost all the large watery heads, the fluid is collected in the bags of the arachnoid and vascular membranes lining the cavities of the brain, so that it is contained, either in all, or the greater number of them, at the same time, which is most frequently the case; or in one of them only. Serum effused from the arachnoid and vascular membrane (pia mater) may thus be situated:—1st, In the sub-arachnoid cellular tissue; that is, between the arachnoid of the pia mater and this vascular membrane: 2d, In the great cavity of the arachnoid around the encephalon: 3d, In the different ventricles, and even in the cavity between the two folds of the septum lucidum (BRESCHET). The quantity of serum effused in these situations varies remarkably. In *congenital and chronic cases*, it is sometimes uncommonly great, filling up and distending enormously the cranial cavity; impeding or arresting the development, altering the form, and even injuring or destroying the texture, of the cerebral substance, which is expanded in the form of a sac; that part of it above the ventricles sometimes consisting of the meninges merely. In *acute hydrocephalus*, the effusion takes place in a few days, and to a much less extent; and in *serous apoplexy* it may occur in a few hours. In these latter diseases, however, it is often a matter of dispute, whether the symptoms are more the result of the effusion, or of diminished vital endowment, and the state of circulation of the brain. (See Dropsy of the Encephalon.)

24. *c. Dryness of the arachnoid* is occasionally found after cases of excessive cerebral irritation, and where inflammatory action has been suspected. There can be no reason wherefore deficient secretion should not sometimes occur here, as well as in other serous membranes, as a result of inflammation. An *unctuous* state of the arachnoid is sometimes observed, particularly after erysipelas, abscess of the brain, discharges from the ear, paralysis, &c., and other states of disease, in which there was reason to infer the existence of inflammatory irritation of the membranes of the brain. *Adhesions* of the arachnoid to the opposite surface of the dura mater, by means of a cellular or firm albuminous false membrane, &c. have been already described (§ 13.). *Dark carbonaceous deposits*, similar to those noticed (§ 14.) in the internal lining of the dura mater, are also rarely observed in the arachnoid and pia mater.

Osseous deposits also occur in the arachnoid, and are likewise rare.

25. *B. The PIA MATER* partakes in all the inflammatory states, and their consequences now described in respect of the arachnoid.—*a. The vascularity* of this membrane varies greatly. Sometimes it consists chiefly of engorgement of its veins, imparting to it a dusky or purplish hue, without any sign of inflammatory or other change. Occasionally this congestion is attended with injection of the arteries, and increased redness only, or with these in conjunction with one or more of the lesions now referred more immediately to the arachnoid.

26. *b. Slight effusions of blood*, and patches of *ecchymoses*, varying from the size of a split pea to that of a half-crown, are occasionally found lying upon the surface of the convolutions, and retained between the meshes of the pia mater. This state arises from concussions of the brain, and congestions consequent upon suffocation, poisoning by narcotics, and the advanced stages of disease; also from obstructions in the vessels returning the blood from the brain. A layer of *fibrine* is sometimes, but rarely, observed as a consequence of effusions of blood between the pia mater and brain; the serum and red particles of the effused blood having been absorbed, and its fibrine remaining.

27. *c. The pia mater and arachnoid* are occasionally separated from the convolutions in consequence of concussion; and in some cases, particularly after acute or recent inflammations, they may be removed from the cerebral substance with scarcely any force, or with much less than in health, the vessels being loaded with blood. OTTO thinks that the *easy separation* of the vascular membrane from the brain originates in the effusion of lymph beneath the membrane, loosening its connection to the cortical substance. On the other hand, after chronic inflammation, occurring without effusion under the membranes, but with a considerable effusion into the ventricles, they are often found so *closely adherent* to the convolutions, that they cannot be separated, but in very small fragments, and then not without bringing away with them portions of the cineritious substance of the brain.

28. *d. Patches of yellow albuminous, or albuminopuriform matter*, are sometimes found on the upper surface of the pia mater, between it and the tunica arachnoidea. These patches are usually small; but they are occasionally very large, and diffused over nearly the whole of one hemisphere. Dr. HOOPER has observed them covering nearly the whole of the base of the brain, so as to envelope most of the nerves. This appearance seems to result from a more than usually intense state of inflammation, as all the membranes are found inflamed, and the blood-vessels loaded with dark blood, and to differ but slightly from the effusion of *pus* and lymph already described in connection with changes of the arachnoid. *Ulceration and mortification* are very rare consequences of inflammation of the pia mater. They may, indeed, be rather considered as superficial ulceration and gangrene of the brain. Cases, however, have been met with, sometimes connected with superficial suppuration, affecting chiefly this membrane. (BUZZI, MORGAGNI, DUMREYL, OTTO.)

29. *e. Tumours* often grow from the *pia mater*.

The *scrofulous kind of tumour or tubercles* are not very rare in this situation. When they occur, they sometimes reach a large size, and break down into a puriform fluid, forming circumscribed or encysted abscesses on the surface of the brain. LEIVEILLÉ found them as large as an egg, in an idiot. Cases are also described by EARLE, ABERCROMBIE, OTTO, and others. Tumours of a *sub-cartilaginous structure* are very rarely met with in the pia mater, although occasionally in the *choroid plexus*. They are usually of the size of a pea, round or oval, laminated cartilaginous, in the centre, exteriorly tuberculous, and covered with a delicate vascular membrane.

30. True *encysted tumours* are also sometimes met with in the pia mater. OTTO describes one of immense size,—six inches long by three broad,—found on the right hemisphere of the brain of the Duke of Saxe-Gotha. ESCUVIROL met with a tumour of this kind containing fat; and similar instances have been recorded. *Ossific deposits* and *earthy concretions* have been rarely observed on the internal surface of the pia mater, dipping down into the structure of the brain.

31. *f. Serous cysts*, the hygroma of Dr. HOOPER, consist of a delicate and transparent membrane, filled with a clear, limpid serum. There is in some cases only one, in others two, three, four, or even more. When solitary, they vary from the size of an orange-pip to that of a walnut; but they are seldom much above the bulk of a large pea. When numerous, they are usually much smaller. They are very rare in the membranes of the exterior surfaces of the brain; but they are very common in the *choroid plexus*, where they are frequently in clusters. They have been mistaken for hydatids, but are merely simple cysts, containing a serous fluid. They have likewise been found in the adventitious membranes formed on the surface of the brain. They generally furnish no symptom by which their existence can even be suspected during life.—The *acephalocyst*, or headless hydatid, is seldom or never found in the pia mater. Five species of the *Cysticercus*, or the bladder-tailed worm, namely, the *C. tenuicollis*, the *C. Fischerianus*, the *C. dicystus*, *C. punctatus*, and the *C. Finna*, have been discovered respectively by BRERA, FISCHER, LAENNEC, TREUTLER, and WERNER, either in the pia mater or *choroid plexus*. (Art. CYSTICERCUS, *Dict. de Méd.*)

32. *g. Fungoid, hæmatoid, and other malignant tumours*, are sometimes found in the pia mater and arachnoid; but I believe they are seldom or never met with as a primary disease, but associated, as a consecutive change, with fungoid or malignant disease in some other part of the body. When they grow to any considerable size, they become deeply indented into the convolutions; producing at first irritation, and afterwards, as they increase, symptoms of pressure. When, therefore, such phenomena present themselves, in persons with fungoid disease, we may suspect its development also in the brain.

33. *C. The CHOROID PLEXUS*, and the *vascular plexus* of the fourth ventricle, which are all productions of the pia mater, are often found remarkably *dilated with blood*, and their *vessels varicose*, particularly when the pia mater has its vessels overcharged. The choroid plexus is also sometimes uncommonly *pale and exsanguine*. This generally occurs when considerable effusion of serum

has taken place in the ventricles, especially when the effusion is connected with debility. Sometimes the plexus contains a number of *transparent vesicles* (see §30.), and it occasionally presents a *granulated* or *fleshy* appearance. This has been ascribed to a morbidly enlarged state of the glandular apparatus, with which, in the opinion of some anatomists, this structure is naturally provided. *Gelatinous tumours* about the size of a bean, and surrounded by a cyst, have also, though rarely, been observed in this situation. Tumours of a *cheesy* or *sub-cartilaginous* consistence, the size of a pea, are likewise found, in some rare cases; and occasionally these tumours contain *ossific deposits* in their centres. *Bony* and *earthy concretions* are still more rarely met with in the choroid plexus than in the membranes. All these morbid changes have been most frequently observed in apoplectic, epileptic, and paralytic cases; but they have also been frequently detected where no particular symptom referrible to the nervous system had manifested itself during life.

34. The *membrane which lines the ventricles* is naturally extremely thin and transparent. No blood-vessels, excepting those which ramify over the corpora striata and thalami from their trunks, which pass by the side of the tænia semicircularis, are usually observed in it. The vessels, however, of this membrane are sometimes found much enlarged, and gorged with blood, particularly when a fluid is collected in the ventricles, so as to distend them beyond their natural capacity. In this state the membrane is not only more vascular, but also much firmer and thicker than natural. The septum lucidum is sometimes as thick as the dura mater, and very firm; but more commonly, those parts of the membrane which are thickened and rendered opaque, are also soft and pulpy.

35. *Coagulated albumen* is occasionally found on the surface of the ventricles. It is sometimes met with in layers on the corpus striatum and the thalamus. I have found it of great thickness; and in one case, which recently occurred to me at the Children's Infirmary, it nearly filled both ventricles. *Ulceration* proceeding from inflammation is occasionally met with in this surface, particularly in the corpus striatum. It seems generally to arise from the formation of a small abscess or purulent collection under the membrane, which it ruptures, the fluid thus escaping into the ventricle.

36. *D. Inflamed states of the PIA MATER*, with or without ulceration, puriform secretion, &c., are, as well as other lesions of this description in other parts of the brain, most frequently occasioned by external injuries. Inflammatory irritation, affecting the arachnoid and vascular membrane either of the periphery of the brain or of the cavities, is not an unusual consequence of injuries of a serious character sustained in other parts of the body, as after compound fractures and contusions of the limbs and joints, severe burns, &c. In these cases, a similar state of the membranes, as well as a nearly similar kind of delirium to that which has been called delirium tremens, sometimes occur. Inflammatory states, either with dryness of the membranes, but more frequently with effusions of various kinds, often taken place in the progress of acute diseases, particularly fevers, and the exanthemata; from drunkenness, accidents, concussions, or mental excitement; whilst congestions, effusions, and

infiltrations of blood, proceed generally from interrupted circulation through the heart and lungs, narcotic poisons, asphyxia, &c., and frequently are attended with convulsions, stupor, coma, paralysis, &c. The adventitious formations are usually the result of a cachectic habit of body, as scrofula, deficient vital power, and the vitiation of the system by syphilis, and the cancerous or carcinomatous taint.

37. iii. LESIONS OF THE SINUSES OF THE DURA MATER, AND VESSELS OF THE BRAIN.—*a. Inflammation of the sinuses is sometimes observed, in its advanced stages and consequences, and but rarely at the early periods. In this latter case, they manifest chiefly increased vascularity, and redness of their internal lining, with slight thickening and friability, sometimes with softening, and occasionally with abrasion, and give rise to the following changes, seated immediately within the part of the vessel which is inflamed:—1st, To the coagulation of the blood in contact with, and its adhesion to, the inflamed surface of the vessel: 2d, Subsequent discoloration of the coagulum, and its conversion into a state nearly resembling that of coagulated lymph: and, 3d, The presence of pus, which is usually found in the middle of this coagulum, though not always. Thickening of the membranes forming the parietes of the sinuses is occasionally remarked, and is evidently a result of a slow state of inflammatory action, affecting chiefly the fine cellular tissue connecting the serous lining to the fibrous membrane. Sometimes their parietes are remarkably thick and dense, almost approaching to cartilage, this morbid change being chiefly seated in their connecting cellular substance. Firm fibrinous formations, or coagulated lymph, are also occasionally formed in these vessels; in some cases, conjointly with marks of inflammation in them; the internal tissues of the vessels being red, injected, congested, and of a dark colour; and in others without any very marked appearance of such disease, but with evident thickening of their parietes. In several instances I have observed these formations disposed in the form of false membranes within the sinuses, and adherent to their serous lining. While the more exterior surface of these false membranes, or that next the vessel, is generally firm, the interior of the canal which it forms is soft, and contains a purulent-like matter mixed with a concrete albuminous substance.*

38. In other instances, no fibrous concretions are formed, nor is the vessel perceptibly inflamed, and yet *pus* is found in parts of the sinuses, either distinct and in considerable quantity, or mixed with firm coagula, or with clots of blood, and in small quantity. In these cases there is reason to suppose that *pus* has been carried by the veins into this situation from an adjoining part. In some cases it occurs accompanied with an albuminous-like effusion, more or less concrete, or with firm fibrinous coagula, and an inflamed state of the internal membrane of the vessel. In many, the presence of *pus* is connected with an apparent abrasion, and even ulceration of the internal surface of the sinus; but in others, increased vascularity, with patches of deep redness, or of congestion, with a deep lividity, and occasionally slight thickening with diminished cohesion of the parietes of the vessel, are most remarkable. In all these, there can be no doubt that the puriform

fluid is deposited in this situation from the surrounding inflamed parietes of the vessel.

39. The lesions now described are most frequently connected, in adults, with chronic disease of the bones of the cranium; and, in rarer instances, with disorganization of the brain itself and of its membranes. They are most frequent after fractures of the skull, and external injuries: and I believe that they are occasional consequences of the worst forms of erysipelas of the head; a case of this description having occurred to me, in which inflammation of the sinuses of the dura mater was found upon dissection. They are more common in children, according to my experience, than in any other class of patients; particularly from the age of one and a half or two years to ten or twelve. I have observed the appearances now described in several cases of cerebral disease; or, at least, of cases terminating with the usual symptoms of pressure on the brain, following severe states of porrigo, ulcers of the scalp, and chronic diseases of this structure, particularly in scrofulous, weak, and ill-fed children. The observations of M. TONNELLÉ and of M. RIBES fully agree with my experience as to the pathological relations of these lesions of the sinuses. The sinuses also present a *vermilion colour* of their internal membrane, like that which is sometimes found in the arterial system. This appearance is most probably caused by a morbid state of the blood; and it may be, on some occasions, a *post mortem* change, arising from the staining of the internal surface of the vessels by the colouring part of their contents.

40. *b.* In respect of the *state of the blood* itself in the sinuses, much diversity exists: the quantity contained by them also varies greatly. More frequently they are empty, or nearly so. When they contain blood, it is in some cases dark, semi-fluid, or thick; in others, less dark, and more fluid; in the greater number, either altogether or partly coagulated. In a few, it is separated into a serous or sero-sanguineous fluid, and a fibrinous coagulum having no connection with the parietes of the vessel, the coagulum consisting entirely of the fibrine of the coagulated blood, and not of the albuminous fibrine, or coagulated lymph, already described (§ 36.). In some cases, one or more of the sinuses is filled with a dense, firm, and brown *coagulum*, perfectly continuous throughout; branching even into the veins which open into the sinuses; and not interrupted, soft, and forming variously-sized clots, such as are often found after death. This state of the contents of the sinuses is seldom or never connected with inflammation of its parietes, unless the inflammation has occasioned, by means of the albuminous matter effused, a complete obstruction of the vessel, and, consequently, the accumulation and gradual coagulation of the blood beyond it; being a change in these fluids independent of organic lesions of the parietes of the sinus, unless such lesion occasion obstructed circulation through it.

41. The firm, dense, and continuous coagulum now described is evidently the result of a slow coagulation proceeding in the sinuses previous to death; and, in every instance in which I have observed it, has arisen from obstruction in the return of blood from the sinuses, owing to compression of the jugular veins, by tubercles, scrofulous tumours, or other organic changes obliter-

ating the canals of these vessels, or of the sinuses themselves; or from a stasis of the blood, followed by coagulation in these vessels, arising in consequence of great cerebral congestion, joined with the utmost general adynamia. There is no doubt that the effusion of lymph, in any of its states, or even of purulent matter, will, while in connection with the internal surface of an inflamed vessel, or mixing with the blood in it, dispose this fluid to coagulation; forming a nucleus around which coagulation will proceed, or a point from which it may depart. And such seems to be the source of the more or less extensive and continuous coagula, which we frequently find in connection with inflammatory lesions and formations in the sinuses. But such is not the case here. In the course of an extended experience at the Infirmary for Children, I have observed, in several cases, that this state of dense coagulation of the blood in the sinuses manifestly supervenes before death, owing to the general and local conditions now stated, and gives rise to all the symptoms of more or less complete and sudden compression of the brain, owing to the consequences I am now to notice as arising from it, in common with other causes of obstruction in the sinuses. In cases of this description, if no effusion of blood have occurred, the veins are found generally engorged with dark blood. In some cases, the distension of the veins had given rise to an exudation of blood, or rupture of several of their minute distributions, with copious extravasation of this fluid; and in many, the distension of the veins was accompanied with copious effusions of serum in the ventricles, between the membranes, or in both situations.

42. *c.* The *glandule Pacchioni* are sometimes so much increased in number and size as to obstruct the passage of blood through the sinuses; give rise to the appearances now described; and thus, as the other changes in the sinuses, terminate in some one or other of the apoplectic states. Mr. EARLE (*Medico-Chirurg. Trans.* vol. iii. p. 66.) has observed these glands changed to the appearance of grumous blood, in connection with fungoid disease in the brain. They are more frequently enlarged and hardened; and, occasionally, they cause an absorption of the dura mater, with corresponding depressions in the superincumbent bone.

43. *d.* The *bands* which cross the longitudinal sinus are occasionally more numerous than natural; and they are sometimes thickened, particularly in connection with a similar change of the parietes of the sinus.

44. *e.* The *veins on the surface of the brain* sometimes contain a few bubbles of air; but it is doubtful whether this is a morbid state or a *post mortem* change. They are occasionally filled with *fibrine*, particularly in those cases which presented a corresponding state of the sinuses. *Pus* has also been observed in them, especially in cases of inflammation, with secretion of pus under the arachnoid.

45. *f.* *Ossification* is detected only in the *arteries*; but it occurs in them very frequently, and to a very great extent, particularly in advanced life. The early stages of this change have also been discovered in youth, although rarely. The arteries most commonly found ossified are the internal carotids and the basilar; but the circle of Willis,

and the vessels departing from it, as well as the arterial ramifications which appear between the convolutions, and come out upon the surface, often participate more or less in this morbid state. *Cartilaginous* degeneration is still more extensive, and seems to precede the ossific deposits. *Cartilaginous*, ossific, and *atheromatous* formations in the coats of the arteries of the brain occasion irregular distributions of blood, and interrupted or imperfect supplies of this fluid to some parts of the organ; disposing to aneurismal dilatations, to rupture, and, consequently, to the production of apoplexy and paralysis. In most instances of extravasation of blood in the substance of the brain, these conditions of the arteries exist; and are, most probably, the causes of the extravasation, by disposing to congestion, and rupture from increased action of the heart.

46. *g.* *Aneurismal dilatations* of the arteries of the encephalon are by no means very uncommon: they are most frequently met with in the carotids after they have entered the cranium, in the large branches, and in the basilar artery. They may derange the circulation of the brain, or may occasion effusions of either blood or serum, without themselves having been ruptured; but they more frequently break, occasioning apoplexy. The arteries, particularly those about the base of the brain, and some part of the branches forming the circle of Willis, are also occasionally *obliterated* and reduced to a thin chord.

47. II. LESIONS OF THE SUBSTANCE OF THE BRAIN.—The morbid states of the brain have been investigated in modern times with the greatest success and advantage to practical medicine. The labours of REIL, SERRES, LALLEMAND, WENZEL, GALL, ROSTAN, ABERCOMBE, HOOPER, CRAIGIE, and DUNCAN, have chiefly tended to this advancement; whilst a number of other enquirers have added much of importance, as well as confirmed the observations of more original enquirers.

48. i. INFLAMMATION OF THE SUBSTANCE OF THE BRAIN, — *Encephalitis*, — *Cerebritis* — *A. Acute inflammation* of the brain does not frequently occur as an idiopathic or primary and uncomplicated malady. It is in consequence of previous disease, as fevers, the exanthemata, inflammations of the ears, extravasated blood, tumours and tubercles of the brain, of poisons, and external injury, that it comes most frequently before the pathologist. Resulting from injury, it is generally limited in extent, although intense in degree. The whole brain is rarely or never affected at the same time, but only a part of it; and the disease is seated either in the vascular membrane, or in the cortical substance, or in the medullary matter of the interior parts, of the brain, or in them all simultaneously. The part affected first becomes vascular, and the injection of the vessels proceeds till the cerebral substance displays a red tint, deepening, as the disease advances, until it assumes a reddish brown, and, occasionally, even a brownish or green shade. With this increased intensity of disease, the part becomes softer than natural. The formation of matter, however, is not so frequent a consequence of this form of inflammation as of that of a sub-acute or chronic kind, occurring in persons of a scrofulous diathesis, and unhealthy habit of body, unless when a foreign substance, or piece of bone, has been driven into the brain. Somewhat similar to inflammation

although decidedly different from it, is that state of morbid irritation frequently met with in fevers, especially typhus, eruptive diseases, epilepsy, delirium tremens, tetanus, convulsions, hydrophobia, nostalgia. In these diseases, vascular turgescence and red injection of the brain are usually seen; but not the general red colouring, the spot-like effusion of blood, and the change of consistence, which characterise acute inflammation of this structure.

49. Acute cerebritis occasions violent headach, intolerance of light, acuteness of all the senses, delirium rapidly succeeded by convulsions, coma, and death. When it arises from morbid poisons affecting the system, as in gaol and camp fevers, purulent formations are more frequently met with, as stated by PRINGLE and others. In these cases the symptoms are somewhat varied; the prostration of the powers of life being much greater, and the delirium of a much lower grade. In those diseases, the *post mortem* inspections, when numerous, will furnish examples of the various stages of lesion, from the first appearances of injection of the vessels to the formation of matter, or complete destruction of the part chiefly affected.

50. *B. Suppuration of the brain, — Abscess of the brain, — Apostema cerebri.* — Collections of purulent matter have been often found in the brain, generally as a consequence of inflammation of a sub-acute or chronic kind. Of this the writings of BONET, MORGAGNI, LIEUTAUD, BAADER, STOLL (*Rat. Med.* i. p. 285.), FRANK (*Acta Inst. Clin. Vih.* Ann. 1. p. 75.), PROCHASKA (*Anat. Acad. Fasc.* part. ii. sect. ii. cap. 2.), SCHAEFFER (*Hufeland und Himly. Journ. der Pr. Heilk.* (1809), PORTAL (*Mémoires de l'Acad. des Sciences.* 1780, p. 315.), LALLEMAND, BAILLIE, BRODIE, POWELL, HOOPER, and ABERCROMBIE, furnish numerous examples. The situations of these abscesses vary considerably, as well as the kinds of abscess formed. — *a.* Sometimes the purulent collection is lodged in an irregular cavity, and appears unsurrounded by any distinct cyst. These take place to a greater or less extent, and consist most commonly of purulent matter mixed with flakes of lymph, giving it a slight curdly appearance. They are most commonly found in the anterior lobe of the cerebrum, or in the centres of the hemisphere. Some of the abscesses of this kind seem to consist of several small cavities communicating with each other: these are usually found also in the anterior lobes, the centres of the hemispheres, or near the striated nucleus of REIL. — *b.* The next species of abscess consists of a distinct, firm cyst, or even cysts, as observed by LALLEMAND, and seems to have been the result of a slower process of formation, and of a less acute form of inflammation: it contains purulent matter, and is most frequently found in the centre of the hemispheres, particularly just above the central oval of VIEUSSENS, or at its margin. Abscess of the brain has also been met with immediately below the *cornu ammonis*; likewise near the parietes of the small posterior cornu of one of the lateral ventricles, and just below the unifornic eminence which rises into the interior of this cavity. In one instance only (*North Amer. Med. and Surg. Journ.* 1818.) have the *tubercula quadrigemina*, and pineal gland, been the seat of abscess.

51. *c.* Purulent matter is also found in some part of the brain, infiltrated, as it were, into the cere-

bral substance in the form of a number of minute drops, and occupying a considerable extent, but not lodged in any single distinct cavity: the parts surrounding the purulent infiltration presenting scarcely any other appearance of change, excepting more or less softening, which is always present, and seldom any sign of augmented vascular action. This morbid state is frequently observed as the consequence of the transit of purulent matter into the circulation, which, in some cases, is secreted from the vessels in the substance of the brain, giving rise to the infiltration. This phenomenon takes place much more frequently in the parenchyma of other organs, as of the liver, lungs, and spleen, than in the brain. The infiltration, whether proceeding from this source or not, often passes into the condition of distinct collections, varying in number and size; and sometimes they nearly or altogether communicate. In such cases, the cerebral substance separating these collections seems as if it were softened, or broken down into the purulent matter, and often processes of the cerebral structure, still adhering to the surfaces surrounding these collections, are floating in them, appearing as the debris of a portion of the disorganised brain. In these cases an approach is made to the formation of a regular cavity. In other instances, if the disease is less rapid, or does not destroy life before further local changes take place, a distinct cavity is effected, which, at first, consists of the cerebral substance merely, softened, discoloured, and vascular. M. ANDRAL thinks that the following characters presented by the cavities containing purulent matter are the result of subsequent changes which the surfaces of these cavities undergo, and not the result of an original dissimilarity of structure. As to this point, I think his reasoning inconclusive, and his proofs insufficiently strong. It, however, should be admitted, that the purulent infiltrations, and collections in either of the forms now noticed, are those which take place most rapidly, and which are generally observed in *post mortem* researches, in cases of death taking place soon after the symptoms of cerebral disease had supervened; whilst the encysted form, as I have already stated, are those which manifestly form most slowly.

52. *d.* The different kinds of parietes surrounding the collections of matter in the brain, according to this able pathologist, are, — 1st, The cerebral structure itself, which, in recent and acute cases, forms the only envelope of the purulent collection; but which may assume the following appearances successively, according to the duration of the disease. 2d, A cellulovascular substance, extending over the whole of the internal surface of the cavity, or merely in parts. 3d, A true membrane, which is as yet soft, and flocculent, but yet admitting of separation from the adjoining nervous substance. 4th, A fine membrane, presenting a distinct organisation, and capable of being detached either in pieces or entire. Once arrived at this stage, their internal surface often has the appearance of villousities, whilst sometimes the cyst is composed of two or more distinct layers, which may be detached from each other. In these cases, the cysts are thick, as remarked by Professor LALLEMAND; the internal layer, or cyst, being of a reddish white, and presenting the appearance of a mucous sur-

face slightly inflamed. In a case noticed by this author, in which three distinct layers, or cysts, were observed, the exterior was cellular, adhering to the cerebral substance; the middle one thick and firm; the interior layer closely resembled a mucous surface. MECKEL, however, espouses a different opinion from ANDRAL, as to the formation of abscesses contained in distinct cysts. These are not, according to him, owing to advanced changes in the organisation of the walls of the purulent collection; nor are they to be ascribed to suppuration of the cerebral texture itself; but to inflammation and suppuration of an adventitious structure, developed in the cerebral substance. His reasons for this opinion are,—1st, That those cysts adhere but very loosely to the surrounding cerebral texture: 2dly, That this texture is not hardened, but, on the contrary, softened, immediately around them.

53. The cerebral substance in which the purulent infiltrations and collections of the first grade are found, is generally softened, and, excepting when they arise from the absorption of purulent matter into the circulation, more or less injected. In cases of purulent collections contained in more or less distinct cysts, or membranes, the surrounding structures are often but slightly altered, and occasionally not even perceptibly so. But when the collection has much increased, or continued long, the nervous substance surrounding the cyst becomes irritated, inflamed, discoloured, and softened; and then only supervene those symptoms which evince, unequivocally, the existence of abscess or serious organic lesion: for, up to this period, the abscess may have been proceeding, but so slowly as not to disturb the functions of the organ, until, owing to some determining cause, in conjunction with the changes taken place in the cyst or its contents, or with its size, the substance of the brain surrounding it becomes diseased.

54. Abscesses, whether immediately surrounded by the cerebral structure, or contained in more or less distinct cysts, may vary in number from one to six or seven, each distinct from the other, and seated in various parts of the brain. They may present appearances of ulceration in their parietes; and they may be accompanied by a variety of other lesions of the brain and its membranes, generally in different subjects, but occasionally even in the same case. Inflammatory appearances of the membranes; effusions, serous or albuminous, in either the external or internal surfaces of the organ; softening of the structure, tumours, occasionally hardening, &c.; are their usual attendants.

55. *e.* In respect of appearance, the pus found in the brain differs in no way from that formed in other textures of the body. M. LALLEMAND (*Récherches Anatomico-Patholog. sur l'Enceph.* &c. let. iii. p. 361., let. iv. p. 41.), whose numerous observations of purulent collections in the brain have enabled him to give much interesting information on this topic, states, that he has observed it of a yellowish green tint, yellowish, yellowish white, greenish, greyish, yellowish grey, whitish grey, dirty white, and altogether white. He, as well as ABERCROMBIE, has frequently found it extremely fœtid. This factor of the pus I have observed in several cases of abscess occurring in young subjects, from the extension of inflam-

mation of the ear to the brain. In a case of this description, reported in the *Medico-Chirurgical Review* for Dec. 1830, the factor of the purulent collection was extreme; and the cerebral substance surrounding it greenish, disorganised, and broken down into the contained matter. Abscesses formed within the substance of the brain occasionally make their way to some part either of the external or of the internal surface of the organ; thus they sometimes break into the ventricles, as in the case just now alluded to: when they open upon the periphery of the cerebrum, they occasionally destroy the bone and intervening membranes in its immediate vicinity, before death is occasioned. M. ANDRAL says, that he has observed an abscess of the brain destroy the cribriform plate of the ethmoid bone, and escape externally through the nasal fossæ: and MM. ITARD, LALLEMAND, and others have shown, that abscess of the brain, from an extension of inflammation from the ear, may destroy the petrous portion of the temporal bone, so far as to admit of the evacuation of the abscess by the ear. In cases originating from this source the matter is frequently contained in no distinct cyst, the cerebral structure surrounding it being generally discoloured, softened, and often appearing as broken down into it. Sometimes the meatus externus and internus are shut up by means of fungous granulations preventing the external exit of the purulent secretion, and hence probably, in some cases, diverting it internally. In some cases more than one abscess, in some instances four or five, seated in distinct parts of the brain, have been observed.

56. *f.* Collections of purulent matter have likewise been found by BIANCHI, STOLL, WEICKARD, J. PLANCUS, FRANK (*De Curand. Homin. Morb.* lib. ii. p. 49.), NANNONI, PERRAULT (*Journ. de Méd.* t. vi. p. 389.), and ABERCROMBIE, in the *cerebellum*, generally contained in more or less distinct cysts, "the walls of which were membranous and vascular." Matter, indistinctly defined, has been found also in the *medulla oblongata*, generally in small irregular cavities, "especially in that part of the olivary body which contains the corpus dentatum." (CRAIGIE, *in opus. cit.* p. 386.) Dr. ABERCROMBIE mentions a case where it was met with at the junction of the protuberance.

57. *g.* These collections are evidently the result of inflammation, but of a peculiar and slow character, probably owing to the constitution of those in whom they are most frequently found, and who are generally of the strumous diathesis. The encysted abscess seems to take place very slowly, and to be analogous to what has been commonly called *chronic* or *cold abscess*. The purulent infiltrations occasionally met with in the large nervous masses, as well as in other viscera, from the absorption of purulent matter into the circulation, evidently take place with great rapidity, and are a result rather of morbid secretion, than of inflammation.

58. *h.* Abscess of the brain is very frequently met with as a consequence of purulent discharge from the ear. This affection of the ear, when it has not apparently proceeded from inflammatory sore throat, and the extension of the inflammation along the Eustachian tube, is very generally connected with a sub-acute or chronic inflammation of the dura or pia mater of the brain; and is thus frequently extended to the substance of the brain

itself, terminating at last in abscess in this situation. This has been satisfactorily shown by MORGAGNI, ITARD, POWELL, LALLEMAND, DUNCAN, ABERCROMBIE, CRAIGIE, and others. BONET, and, more recently, Sir B. BRODIE, supposed that the affection of the ear was consequent upon that of the brain, or at least coeval with it; and hence they ascribe the discharge from the ear to the inflammation of the membranes having extended itself from the dura mater of the temporal bone to the tympanal cavities. When abscess of the brain takes place owing to the affection of the ear, they consider it an extension of the inflammation from the membranes internally to the substance of the brain, in consequence either of the unhealthy habit of the patient, or of improper treatment, by suddenly suppressing the discharge, "and converting a chronic external inflammation into an acute internal disease;" the external discharge having been, as it were, arrested and turned in upon the cerebral substance. The only question here is in respect of the particular parts in which the inflammation originates; as to the consecutive phenomena, there seems to be no difference of opinion: and this point can be decided by the symptoms only, and the order in which they occur. If the purulent discharge take place without any previous internal and deep-seated pain, and the dangerous symptoms follow upon the suppression of the discharge, we may infer that the disease has commenced in the ear, and extended itself to the membranes and brain itself. This is, perhaps, the most frequent procession of the morbid phenomena. But, occasionally, a different course is manifest, especially in delicate children, and patients of a strumous diathesis. In these, symptoms of disease of the brain or its membranes are very manifest before the discharge takes place; and when it does take place, either the patient recovers, under judicious management, or, upon the disappearance or suppression of the discharge, a sudden exacerbation of the symptoms is observed, with delirium, coma, convulsions, &c. followed by death. Such is the result of my experience in a very great number of cases which have come before me; so that I am led to conclude that, whilst the opinion adopted by MORGAGNI and his followers, on this question, is often correct, that espoused by BONET and BRODIE is not wholly without foundation.

59. But it is not infrequently observed, (and I have met with several instances in grown up persons,) that patients have been occasionally liable, for years, to a puriform discharge from the ear,—occasionally from childhood, with little remission, and with little or no further ailment. This sometimes gradually diminishes, or suddenly disappears; when either soon afterwards, or not until several months subsequently, or even after a year or two, dangerous symptoms of diseased brain supervene, and rapidly advance to a fatal termination; and upon dissection, inflammation of the membranes of the brain of the same side of the body with the affected ear is observed, and in the substance of the hemisphere is found a large purulent collection with inflammation and softening of the cerebral matter surrounding it, the cavity presenting an irregular soft surface.

60. The following cases strongly illustrate this:—1st, A young gentleman had, from childhood, a

slight purulent discharge from the right ear, until nearly the period of puberty; about which time it gradually disappeared. He had nearly lost the sense of hearing on that side. He went into the public service, in which he continued for several years, until, about the age of thirty, he was suddenly seized with intense pain of the head, fever, followed by paralysis of the whole left side of the body, insensibility, involuntary motions, coma, shortly terminating in death. On examination, thickening of the membranes of the right side of the brain, with adhesions, softening of the cerebral structure, and a purulent collection nearly in the centre of the middle lobe of the hemisphere, were found. I very recently witnessed a nearly similar case, to which I was called by a neighbouring practitioner; and a third case, in which I had ventured to predict similar lesions in a person advanced in life, but which we were not permitted to verify by a *post mortem* inspection.

61. Abscess of the brain consecutively on purulent discharge from the ear, is most frequently observed in young subjects, particularly in those of a strumous diathesis. From what I have said, it must not be inferred that abscess of the brain is the only unfavourable consequence, or even the most frequent one, owing to an extension of the inflammatory action from the ear or cerebral membranes; for other lesions accompany it. But, whether the abscess proceed from a gradual extension of disease, as now stated, or be a vicarious result of the suppression of the external discharge,—in which light it may sometimes be justly viewed,—there are generally found, upon examination of the surrounding parts, increased vascularity, softening of the cerebral substance, and an irregular, soft, and vascular cavity, containing the purulent matter. Added to this, there are also inflammation, thickening, and suppuration of the membranes; the pia mater being injected, and covered with lymph; the dura mater thick, opaque, dark coloured, more readily torn, and detached from the bone underneath it, which is also discoloured, and sometimes carious.

62. Abscess of the brain is very often a consequence of external violence; but it is one which takes place at extremely indefinite periods from the receipt of injury, and which often has little or no relation to the extent of the external mischief. The period which elapses from the external violence to that full development of the abscess which is incompatible with the duration of life, according to the observations of PIGRAY, MORAND, PROCHASKA, THILENIUS, HOME, DENMARK, and others, varies from two or three months to as many years. A case which I had an opportunity of observing in a public institution, and in which the operation of trephining had been performed, presented a large abscess in the hemisphere, underneath the seat of injury, between three or four years from the time at which it had been sustained. The perforation made by the trephine was completely filled with ossific matter, which extended in a radiated manner from the edges of the perforation towards its centre.

63. Dr. BAILLIE says, that when suppuration of the brain takes place from internal causes, it is generally in the substance of the organ; but when it arises from external violence, it affects only the surface. But as Dr. CRAIGIE has very

justly remarked, this distinction does not always hold good, and requires modification.—“1st, Where a long interval elapses after the infliction of the injury, the collection of purulent matter is almost invariably deep seated. 2d, In like manner, when the injury operates in the manner of counterstroke, the collection is also often within the substance of the organ.” 3d, In some instances of suppuration after injury, the collection does not take place at the part where the blow struck the skull, but either in the line of the force passing through the brain, or in some of the lines into which this force may be resolved. 4th, It is chiefly when this force has been directly expended on the part, *i. e.* when the bone has been immediately broken, and its membranes injured, that suppuration takes place on the surface of the brain: it is then the result rather of the injury of the membranes, especially of the pia mater, than of the cerebral substance itself.

64. Suppuration may occur in any part of the brain; but it is most frequently met with in the hemispheres, as shown above (§ 50.). Its effects vary exceedingly, according to the situation and extent of the purulent collection; but are not essentially different from those which follow upon the slow effusion of blood, the presence of tumours, or other morbid formations. I have already hinted at the occurrence of suppuration in parts of the brain in the course of fevers, especially those which are of a malignant character, or which are complicated with inflammatory action of the brain. Such occurrences have been observed by PRINGLE, BORSIERI, EISFIELD, PLOUQUET, CLUTTERBUCK, MARCUS, JACKSON, and MILLS, and many others. But this falls under the pathology of, and morbid appearances in fevers, where the subject has received due attention.

65. *C. Ulceration.*—To ulceration of the brain authors have attached no precise idea, they differing widely as to what should constitute ulceration of the cerebral texture. According to the opinions of some, those solutions of continuity, sometimes observed in the most advanced degrees of pulpy destruction of the brain, about to be described (§ 72.), are nothing else than ulceration; and certainly, if there were appearance of any considerable loss of substance by absorption, the lesion would be legitimately ulceration. The case recorded by MORGAGNI (*De Sed. et Caus. Morb. ep. xi. pars ii.*), in which he described the *corpus striatum ab reliquo cerebro omnino separatum inventum est*, which is so singular, may be referred to ulceration. By ulceration of the brain, Dr. CRAIGIE understands destruction of part of either of its surfaces, “so as to present a hollow or depressed surface, rough, irregular, and covered partially either with bloody or albuminous exudation.” This seems sufficiently precise; and excludes those doubtful cases of ulceration sometimes consequent upon effusions of blood, the advanced stages of softening of the organ, and the formations of abscesses existing in the substance of the brain, where, although a breach of continuity of structure is produced, yet the removal of it by absorption cannot be demonstrated. Cases of this description are more legitimately examples of pulpy destruction, or suppurative disorganisation, than of ulceration. With this limitation of ulceration and erosion to the various internal and external surfaces of the brain, M. ANDRAL

agrees with Dr. CRAIGIE. This species of lesion, although not of frequent occurrence, is yet occasionally met with. Besides the case given by MORGAGNI, and already referred to, another is mentioned by him in the same epistle. Instances of this disease have also been recorded by BONET (*Hist. Anat. Med. part iii. Ob. 108. 138.*), WEPFER (*p. 212.*), MORGAGNI (*Epist. Anat. Med. iv.*), LIEUTAUD (*Hist. Anat. Med. let. iii.*), SENAC, VALSALVA, PORTAL (*Anat. Méd. t. iv. p. 98.*), HOWSHIP (*Med. and Phys. Journ. March, 1810*), ANDERSON (*Transact. of Royal Soc. of Edinburgh, vol. ii.*), RIDLEY, HALLER, STOLL (*Ratio Med. pars iii. p. 122.*), POWELL (*Case 6. Transact. of College of Physicians, vol. v. p. 96.*), and SCOUTETTEN (*Archives Gén. t. vii. p. 31.*), who have met with it on the convoluted surface of the brain, on the foliated surface of the cerebellum, and in the surface of the ventricles,—parts in which this morbid change is chiefly found. As shown by HALLER (*t. iv. p. 351.*), STOLL, and SCOUTETTEN, ulceration of any part of the brain's surfaces is always attended with an inflamed, or otherwise unsound state of the pia mater, and occasionally with softening of the parts underneath, sometimes limited to the grey substance, but at others proceeding further. In the two cases recorded by M. SCOUTETTEN, the adjacent brain was somewhat softened, and in one of them of a wine lees colour. The ulceration in the first case existed on the interior surface of the right anterior lobe, and presented a hard, dry, irregular, yellowish surface, thirteen lines long and eleven broad, with singularly indented edges. This patient died with symptoms of irritation of the digestive canal, and of the brain. He experienced a constant acute pain at the bottom of the orbits. In the second case, the extremity of the posterior lobe presented two small ulcerated patches, one much larger than the other, and of an oval form. They penetrated no deeper than the cortical substance. This patient had been seized with gastro-intestinal irritation, and complained of no pain in the head. During the latter stage of his disease, he became delirious. In both these cases the surrounding pia mater was injected, and somewhat eroded; so that we may infer from these, and other cases upon record, that ulceration of the brain is a consequence of circumscribed inflammation of the pia mater.

66. The existence of ulceration of the brain is indicated by headach, partial convulsions, sometimes epilepsy, palsy, loss of memory, hebetude, coma, and exhaustion. In some cases the headach is intermittent, and the palsy is generally on the side opposite to that in which the lesion is found. In the case recorded by Dr. T. ANDERSON, and in which most of the symptoms now noticed were present, there was a superficial loss of substance from ulceration, two and a half inches long, one and a half broad, and nearly an inch in depth, situated on the upper part of the right hemisphere of the brain. In the bottom of this cavity were found some thin laminæ of a brownish matter, with stony concretions, some of which broke into sand upon the slightest touch.

67. *D. Sphaclation or mortification* of the cerebral substance is rarely met with, and chiefly as a result of external injury, when it has been

bruised and acutely inflamed. In this state of disorganisation, the cerebral substance is dissolved, of an orange brown colour, or of a greyish black, and fœtid. This alteration seems to be rarely produced by internal causes, and is to be distinguished from the pulpy softening of the organ. Dr. ABERCROMBIE, however, considers this latter change to be identical with gangrene.

68. ii. SOFTENING OF THE BRAIN.—*A. From serous infiltration,—Edema of the brain.* Infiltration of the substance of the brain with a watery fluid has been noticed by GUERSENT and ANDRAL,—by the former in children, by the latter also in adults. In these cases the serum may be diffused in the nervous substance, or contained in more or less distinct cavities. This change is most frequently observed in the white central parts of the organ. It has not generally been remarked in connection with any particular symptom; but it has, in a few instances, co-existed with dropsy of the ventricles; and, in adult subjects, with general leucophlegmasia and cachexia.

69. *B. Simple diminished consistence of the brain, without change of structure,—Malakencephalon (CRAIGIE),—* seems to be a different state of the organ from that which constitutes the *ramollissement*—softening, or pulpy destruction of the brain. In this latter more or less disorganisation is manifest, and generally some change in its colour; but the former is merely diminished consistence, greater flaccidity, and decrease of its natural firmness, toughness, or tenacity, and of that clamminess or viscid feeling which it usually communicates to the touch. This state is commonly attendant on low or malignant fever, and on chronic diseases, particularly pulmonary affections, marasmus, diabetes, dropsies, mesenteric and visceral affections. It generally affects the whole organ, and, indeed, the whole cerebro-spinal axis; whereas the pulpy destruction of the brain is more or less limited in extent, affecting parts of the organ in a particular manner.

70. In *dropsies*, the brain is often flaccid, more easily lacerated, and of diminished consistence throughout. This state proceeds either from diminished nutrition of the organ, or from an interstitial deposit of serous fluid with its minute atoms, and defective vital cohesion of its substance. The proper texture of the part is not otherwise changed. *Diabetes* sometimes occasions a similar state, and most probably from diminished nutrition added to a deficient vital cohesion of the structure. In *pulmonary consumption*, and in chronic bronchitis, the brain is very commonly found softer than natural throughout; and this softness is the more marked, the more chronic the pulmonary affection has been, and the more complete the emaciation. May not this state be considered as analogous to emaciation of other parts? the molecules of matter removed by interstitial absorption of the texture of this organ being replaced by a serous effusion, owing to the cranium being a shut cavity, which must necessarily, during the life of the subject, always be in a state of repletion. In such a case, the density of the brain is actually diminished. MECKEL states, that he found a cube of six lines, taken from the brain of a man dead of phthisis, $1\frac{1}{2}$ grain lighter than the same bulk of a sound brain. Dr. MONRO has found the brains of condemned felons extremely soft, particularly inter-

nally (*The Morbid Anatomy of the Brain*, vol. i. p. 35. and 100.). LITRE, however, states, that the brain of a felon, who committed suicide, was extremely dense and firm (*Histoire de l'Académie Royale des Sciences*, Ann. 1705.). TULPIUS, KERRINGIUS, KING, SCHEIDE, MORGAGNI, GREYDING, &c. have found the brain frequently soft and flaccid in fatuous persons, as well as in epileptics, and epileptic maniacs. GREYDING (*On Ludwieg's Adversaria*, t. ii. part iii. p. 533.) found in about one half of the last named class of subjects, the brain very soft throughout, particularly in its central parts; and Dr. HASLAM's observations (*Observations on Madness and Melancholy*, 2d edit. Cases, 4. 10. 18. 25. 28. 30. 37.) in some degree confirm these statements. But it should not be overlooked, that the brain of epileptics and maniacs is found also more than usually firm. The diminished consistence of the brain of condemned felons has been attributed to confinement, inactivity, and low diet. Whether these may have a greater influence in causing it than the mental distress to which these persons are reduced, it may be difficult to determine; but if the former be the cause of this state of the organ in felons, it may be equally so in maniacs, who are generally also subjected to confinement and low diet. The diminished consistence now described is more or less universal, although more remarkable in particular parts, and it generally affects the whole cerebro-spinal axis. Whereas the morbid softening, or pulpy destruction, about to be described, is generally limited in extent. The former also seldom presents any very sensible change from the natural colour of the part; whereas with pulpy destruction there is a more or less evident discoloration.

71. *C. Pulpy destruction,—Softening,—Ramollissement,—Encephalitis sub-acuteus,—Cerebritis sub-acuteus et chronicus.*—Softening of the substance of the brain has generally been ascribed to a sub-acute inflammatory action, especially by MORGAGNI, ROSTAN, LALLEMAND, BOULLAUD, PINEL, OLIVIER, and VELPEAU, to whom we are chiefly indebted for having directed attention to this particular lesion. There are others, however, as RECAMIER, who consider this change as the effect of a morbid nutrition of the part, rather than as a result of inflammatory action. By softening of the brain, must not be understood that soft state of the organ which is always present in early infancy, nor the less consistent state of the organ sometimes observed in some chronic diseases, and in certain forms of fever, and already described. It should also be recollected, that all parts of the brain possess not the same degree of firmness; for, if the mesocephalon be as soft as a lobe of the cerebellum, it is undoubtedly in a morbid state.

72. Softening of the brain presents various degrees. The least change of consistence of the part can be recognised only when it is touched. In a more advanced degree, the softening is obvious to the sight. In a still farther advanced grade, the cerebral substance is nearly liquid, and has almost entirely lost its organisation; and in its place there is a mere loose cellular substance, soft and gelatinous, appearing as the original matrix of the structure; and in the last and most advanced stage of all, there is a perfect dissolution of the part, and breach of continuity.

In the cases of this description published by MM. RULLIER and VELPEAU, the disorganisation was so complete, that the filaments of the delicate cellular substance, forming, as it were, the matrix of the structure, were suspended in the middle of the diffuent matter into which the cerebral substance was changed. In the case observed by M. VELPEAU, the solution of continuity was still more complete. From the inferior margin of the mesocephalon to the base of the pyramidal bodies, a substance entirely liquid, which no longer retained the appearance of nervous substance, occupied the place of the bulb of the chord; and through the whole of this space there existed neither arachnoid nor pia mater.

73. The softened portion of brain presents various shades of colour. 1st, It may be of the natural or healthy colour of the part,—even although the softening has advanced to such a degree as to form a diffuent pulp (ANDRAL, LALLEMAND). 2d, It may be perfectly colourless; of a dull white resembling milk; and occasionally the whiteness of the part assumes a clear, or brilliant hue. 3d, The shades of colour sometimes are the following:—a rose tint, an amaranthine red, reddish brown, the colour of wine lees, violet, yellowish, greenish yellow, light grey, and dark grey. Besides the above appearances, the softened part of the brain may be,—1st, The seat of effusions of blood, which are sometimes small, relatively to the degree of softening, or to its extent; at other times very considerable compared with the softening itself: 2d, Pus may be infiltrated throughout the part which is softened; or the pus may exist in it in the form of one or more distinct collections. M. LALLEMAND considers, that in all softenings of the brain of a white colour, this appearance is owing to the infiltration of purulent matter through the softened structure. MM. ROSTAN and ANDRAL espouse an opposite opinion, on the grounds that, in many softened portions of the brain of this shade, no pus could be detected. The softened part of the brain is generally inodorous; but M. BILLARD has remarked, in the case of an infant, the smell of sulphuretted hydrogen. Softening, attended with the odour observed by this author, seems to have constituted what was called, by the older writers, gangrene of the brain.

74. There is no part of the brain or cerebellum in which softening has not at some time or other been detected. Generally those parts which are most obnoxious to hæmorrhage are most liable to softening, such as the optic thalami, and the corpora striata, and the parts in their vicinity. It also as frequently affects the cortical substance, as the medullary texture. In the cerebral hemispheres, the softening may be seated in the cortical substance of the convolutions, the white medullary structure remaining unchanged, where it may often escape detection, owing to such limitation; and it is usually an attendant upon active inflammation of the membranes of the brain. When the grey part is softened, it generally separates along with the pia mater, on attempting to raise this membrane. When softened, this portion is commonly also redder than natural; sometimes, on the contrary, it is paler than common. The medullary structure situated above the lateral ventricles is very often the seat of this species of lesion. This mass may be altogether softened,

or in a few small points merely, each point being quite isolated from the other. The symptoms, however, resulting from this smaller extent of morbid change may be as severe as those arising from the more extensive and more intense lesion. When one of the hemispheres is softened near to its external surface, the circunvolutions are flattened, and often evince a species of fluctuation. M. ANDRAL has remarked, in some cases, the existence of softening of the parietes of the ventricles, with the presence of a turbid fluid effused into them. (*Anat. Pathol.* t. ii. p. 802.)

75. The optic thalami, the striated bodies, and parts in the vicinity of these; the cornu ammonis, and the eminences in the interior of the digitated cavities of the lateral ventricles, the commissures of the hemispheres (*corpus callosum, septum lucidum, &c.*), have all been observed the frequent seats of softening; sometimes limited to one or other of them only, at other times extending to two or more, and occasionally co-existing with signs of inflammatory action, or with effusion of a serous fluid into the ventricles. Softening of the other parts of the encephalon is not so often met with, as of those now enumerated; yet has it been seen in the mesocephalon, in the various parts of the cerebellum, in the medulla oblongata, and spinal chord.

76. Softening of the brain may be limited to one part, or it may exist in several parts, even in both hemispheres, in the same case; and it may affect these different parts at the same time, or successively, either as respects the brain merely, or as regards the whole cerebro-spinal axis. Instead of being partial, which is its usual form, the softening may be so general, and to so intense a degree, that the brain is almost reduced to a pulpy matter, evincing scarcely any appearance of organisation. So general and great a change is very rarely met with in the adult; but it is occasionally observed in infants. M. BILLARD has met with ten instances of it, and I have also found it in some cases of young children: the odour of sulphuretted hydrogen, first noticed by M. BILLARD, was sensible in these; and he found it present in all his cases, which were chiefly of infants only a few days old.

77. Softening of the cerebro-spinal axis is met with in patients of all ages. According to M. ROSTAN (*Récherches sur Ramollissement du Cerveau*, 2d edit. p. 155.), whose attention has been directed, at the Salpêtrière, to this lesion in a special manner, it is very common in old subjects; even more so than sanguineous apoplexy. The researches of LALLEMAND, ANDRAL, and others go to confirm this opinion, and to show that it is also common during early and middle age, although less so than in old age. And I perfectly agree with M. BILLARD in considering it common in children, especially infants. He believes, and I think with justice, that it commences in some cases even before birth.

78. There still remains an important question to be discussed, namely, what is the origin and nature of the softening which has now been described? M. LALLEMAND conceives that it is a constant and necessary result of an acute, sub-acute, or chronic inflammatory irritation of the part. M. ROSTAN, who has examined this subject with great care, and viewed it in various lights, as respects both the morbid appearances

and the symptoms accompanying them, concludes at last by confessing its difficulty, and considering this change as analogous to senile gangrene. Before the question can be entertained with precision, we should previously enquire with what other morbid states of the system generally, and of the brain in particular, has softening been found allied? 1st, It has been observed by JEMINA, BLACK, myself, and others, to supervene during fevers, especially those of an epidemic and malignant character. 2d, It has been seen connected with puerperal disease of a malignant nature; and with epidemic and infectious erysipelas. 3d, It has been found in cases of scorbutus, and to occur in persons of an unhealthy and cachectic habit; also in those whose powers of life have been exhausted by bad living and excesses.

79. As to its relation to other lesions of the brain, I may state that it is often found surrounding *extravasated blood* in the brain, and intimately connected with this effusion. The softened part is then generally of the colour of wine lees, of a brownish hue, sometimes tending to green, or of a grey or ash tint. But what is the nature of this connection? M. ROSTAN contends, that the softening precedes and is always the cause of the effusion, owing to the destruction of the minute capillaries at the point where the softening is greatest; whilst Dr. CRAIGIE and others consider the softening surrounding the effused blood as the consequences of such effusion; and chiefly because, "in cases in which death takes place early, the pulpy disorganisation is less complete than in those, in which it takes place at a later period. In short, the extent of the disorganisation is proportionate to the interval which elapses between the effusion of the blood and the period of death." But is this the fact? It certainly is not in accordance with my experience, for I have observed no such relation; but have found recent effusions surrounded by as great, and even a greater, extent of softening as effusions of an older date.

80. Pulpy softening may be the attendant upon a *coup de sang*, or sudden congestion of the venous capillaries of some part of the brain. This is considered to be the case in softenings with the reddish, amaranthine, crimson, or reddish brown shades of colour. But is the softening a consequence, or a cause of the injection? May it not be a state of the vessels preceding that of effusion? These are questions which large experience and deep thought will not readily decide. Dr. CRAIGIE thinks that the softening is a consequence of the blood-stroke; but I cannot agree with him, merely because the reasons for a contrary opinion are quite as strong as those which may be urged in its favour. It has been often found accompanying hydrocephalic effusions, by ROSTAN, LALLEMAND, BILLARD, OTTO, ANDRAL, and by the author. It is then generally of the lighter shades of colour, and not great in degree. Is it here a consequence or a cause of the serous effusion? It may be either. I am more inclined to consider both lesions as being often coeval, and, whether consecutive or not, depending upon a similar state of the vessels and vital manifestations of the organ and system generally.

81. Softening, or pulpy destruction of a portion of the brain, has likewise been found sur-

rounding tumours and abscesses, by MORGAGNI, SANDFORD, MECKEL, LALLEMAND, BLANE, YELLOWLEY, POWELL, &c., and presenting almost every variety and depth of shade already noticed. In these cases, especially in those where purulent matter is lodged in the substance of the brain, without any intervening cyst or membrane, the softening often amounts to disorganisation, and is more clearly attributable to inflammatory irritation. When it is found subsequently to injury of the brain, external violence, and inflammation of the brain and its membranes, its nature and origin are most manifest. That it does supervene in this way, is shown by FANTONI, MORGAGNI, LE DRAN, SCHNUCKER, O'HALLORAN, DEASE, ABERNETHY, THOMSON, HENNEN, ABERCROMBIE, and others. The apparently unequivocal origin of this lesion in inflammation, under these latter circumstances, induced MORGAGNI, LIEUTAUD, JEMINA, and more recently BAILLIE and ABERCROMBIE, to consider it as analogous to gangrene in other structures.

82. But it should be kept in recollection that this state of the cerebral structure, although often preceded by signs of inflammation, and exhibiting in the parts surrounding it inflammatory appearances, is often neither preceded by the one, nor accompanied by the other, but, on the contrary, with a directly opposite train of phenomena and state of parts. In these opposing cases, what is the origin of the disease? Are we to infer, with RECAMIER, an entirely opposite origin to that of inflammatory action, and that as the softenings observed in the brain betray a variety of characters, therefore they ought not strictly to be referred to a single unvarying source?

83. From what I have seen of, or read concerning, this lesion, I should infer, in respect of either of its most manifest conditions, that it is an effect of different states of morbid action, but most frequently of a form of sub-acute inflammation, characterised by deficient power and loss of the vital tone and cohesion of both the vessels and the substance of the brain,—that it is the result of deficient vitality of the extreme capillaries and cerebral structure, occurring either primarily, or in consequence of previously excited action. The circumstances in which it is observed; its occurrence after injuries and bruises, from the pressure of tumours, &c., and during the progress of malignant diseases, show that it is not produced by a sthenic or healthy form of inflammatory action; but by that unhealthy, disorganising and diffusible kind observed in cachectic habits, or in persons whose vital powers are much reduced. At the same time, I think it cannot be denied, that it sometimes originates in a different way, is preceded by no signs of inflammatory irritation, nor is attended with inflammatory appearances, but is a consequence of structural lesions of the cerebral arteries, and of diminished, or altogether lost, vital power and cohesion of the part affected.

84. iii. HÆMORRHAGE.—*Sanguineous effusion* may occur in a primary form, but more commonly from some morbid state of the vessels, or of the substance of the brain itself. It may take place in any part of the organ, but much more frequently in some situations than in others.—*a.* Blood is effused on the external surface of the brain, either in small quantities beneath the pia mater, in one or two anfractuosities; or in an

uniform layer, even extending over the whole of an hemisphere in rare cases.—*b.* It is sometimes found in large quantities in the ventricles; but it generally has escaped into them, owing to laceration of the cerebral substance in which the extravasation takes place.—*c.* The hæmorrhage most frequently is in this substance. M. ANDRAL states, that in 392 cases of hæmorrhage in the brain, its actual seat was in some part of the cerebral substance in as many as 386. Of these, 202 occurred in the *corpora striata*, and *thalami optici*, and parts in the hemispheres, on a level with these places. The cavities formed by the extravasated blood vary in size, from that of a small pea, to the greater part of the extent of a whole hemisphere. When the effusion is very large, it generally ruptures the parietes of the lateral ventricles, sometimes tearing the septum lucidum, and destroying the fornix. In other cases it may make its way to the exterior of the brain, and spread itself over the cavity of the arachnoid.

85. The number of hæmorrhagic cavities found in the brain vary from one to many. When several are found in the same brain, they generally present different appearances, owing to their having been formed at different periods. This is generally the case when the patient has experienced several attacks of apoplexy or palsy. M. ANDRAL remarks that effusion of blood seldom occurs in the cerebellum without appearing also in the cerebrum, whereas it may take place in any part of the cerebral hemispheres without occurring elsewhere. I have stated in the article on APOPLEXY, the periods of life at which hæmorrhage in the brain is most frequently met with. Instances have occurred to MM. ROCHOUX, BILLARD, SERRES, GUERSENT, and myself, in which it has taken place at the unusual periods of infancy and childhood. The changes that take place in the effused blood, in the cavity containing it, and in the substance of the brain after hæmorrhage, comprising the reparative processes consequent upon it, are fully decribed in the article APOPLEXY (§ 35—39.). I have there shown that the cysts remaining after the coagula have been absorbed, sometimes disappear altogether by adhesion of their parietes. Some pathologists suppose that the cerebral fibres in those cases are directly united, and refer to the experiments of FONTANA, HAUGHTON, MICHAELIS, and MAYER, who had shown, in opposition to ARNEMANN, that the filaments of divided nerves are, after a time, directly produced in the direction of their axis across the cicatrix. But intimate examination of the cicatrix of a lacerated portion of brain, or of a hæmorrhagic cyst, shows that this does not take place in the medullary structure of the brain. (See APOPLEXY, § 53.)

86. iv. HYPERTROPHY AND ATROPHY OF THE BRAIN.—*A.* The brain occasionally presents lesions evidently connected with a modification of the nutritive process. In such cases, the consistence and size, either of the whole, or of certain of its parts merely, are altered. Changes of its consistence are more frequent than of its size, and both are occasionally conjoined. It should not be overlooked, however, that the consistence and size of the organ are modified from the usual standard of middle age, at both the earliest and most advanced epochs of life; and that these

modifications, as being its natural conditions at those terms, are to be distinguished from the alterations occasioned by disease. One hemisphere may also differ from the other, in respect both of its volume, and the form and size of its convolutions, owing to original conformation, without occasioning any appreciable disorder of function.

87. The brain continues to increase in size until manhood; from this period until old age its volume continues the same; but with extreme age it somewhat diminishes in bulk. This is, however, not an uniform occurrence, for disease may have cut short existence before the period had arrived, at which the organ would have undergone this change. According to CAZAUVIELLH, the longitudinal diameter of the brain of an old man, compared with that of one in early life, is 6 inches 1 line French measure for the former, and 6 inches 4 lines for the latter; whilst the transverse diameter is 4 inches 10 lines, and 5 inches respectively. M. DESMOULINS (*Anat. des Syst. Nerv. &c.* t. ii. p. 620.) found that in persons above seventy years of age, the specific gravity of the brain was from one twentieth to one fiftieth less than that of the brain of persons just arrived at manhood.

88. The convolutions of the brain are scarcely developed at birth, or even until the expiration of the first year. In old age they again become less distinct and prominent. In the brain of the full grown young subject, they vary in thickness from three to five lines, whilst they are usually about two or three lines in old persons. They present the greatest diversity in respect to their number and length, and the depth of their anfractuositities in the adult: in general they are the most marked and developed in the largest brains. Several physiologists in France are of opinion that the development of the faculties of the mind has a very intimate relation with the extent and number of the convolutions of the hemispheres, and the depth of their anfractuositities.

89. But it is important for the physician to know that not only may the whole encephalon experience a diminution of its bulk and specific gravity with old age, but that this diminution may be particularly apparent in certain parts of it in preference to others; and it is presumed, that this change may sometimes commence in one portion previously to others, or may affect it alone, so as to disturb its functions without being so evident upon dissection as to attract notice. The comparative length of the following parts of the encephalon of subjects just arrived at puberty, of those in the prime of life, and of aged persons, is here given, as furnished by M. CAZAUVIELLH in French measure:—

	Persons at Puberty.		In the Prime of Life.		In Old Age.	
		in. lines.		in. lines.		in. lines.
<i>Thal. optici</i> -		1 5½		1 6		1 4½
<i>Corp. striata</i> -		2 6		2 6		2 4½
<i>Corp. callosum</i>		3 4½		3 5		2 7
<i>Mesocephalon</i> {	length	0 10		0 11		0 10½
	breadth	1 0		1 1		1 0
<i>Cerebellum</i> {	length	2 2		2 3		2 3
	breadth	3 9		3 9		3 9

90. From these data it will appear, that the cerebellum is the only part of the encephalon which is not diminished by old age. But it may be asked, do the large nervous masses experience

any diminution of volume analogous to that which the muscular textures and other parts experience in chronic diseases? In answer to this, M. DESMOULINS states that the brain, although atrophied in the manner stated above by old age, suffers no diminution of its bulk, whatever may be the degree of marasmus to which the individual may have been reduced. In all such cases he has also found the brain of the same specific gravity; and, to this predominancy of development which the brain thus has acquired over all other organs, he is inclined partly to impute that nervous susceptibility and excitation, which are common to the last stages of those maladies. It ought, however, to be borne in recollection, that, although the nervous centres may not undergo any change in bulk or specific gravity in consequence of those diseases, they often experience a very marked diminution of their consistence, as we shall have to show in the sequel. Having been made acquainted with these modifications of the nutrition of the encephalon which it undergoes at the different epochs of life, we are the better able to recognise those which are the result of disease.

91. *B. Hypertrophy, or morbidly increased bulk of the brain*, is very rarely met with. This state of the organ is to be distinguished from the apparently augmented bulk, arising either from increased vascular action, or congestion of the vessels. It appears to consist of an actual increase of the molecules of matter composing the proper tissue of the organ, and not of an injection of the minute vessels distending its structure. Although this condition of the brain seems to have been known to MORGAGNI, it is to LAENNEC that we are indebted for precise information respecting it. He stated (*Journ. de Corvisart, &c. t. ii. p. 669.*), that, upon opening the heads of patients who had been thought to have died of hydrocephalus, he found no fluid effused; but the brain presented appearances of great compression, which he could attribute to no other cause, than to a too active nutrition of its structure, giving it a bulk too great for the bony case containing it. In children especially, who had died in convulsions, or who had been subject to epilepsy, this disproportion between the capacity of the cranium and the bulk of the encephalon has been witnessed by him on several occasions, the convolutions of the hemispheres being flattened, and apparently squeezed against each other. M. DANCE has also described this state of the brain (*Répertoire d'Anatomie, t. v. 1828.*), and furnished some cases in which it was observed. It is chiefly met with in children or young subjects, and is, I conceive, of very rare occurrence, since, from amongst the great many thousand cases of children's diseases which have come before me, I have only remarked three cases in which it was unequivocally present. In these it presented the following characters:—The convolutions of the hemispheres were extremely flat, and closely pressed against each other, so that the separations between them were scarcely apparent. The cerebral structure was firm, and, when incised, was dry, and more than commonly destitute of blood. The ventricles seemed small, were closely pressed together, and almost dry. The bones of the cranium were either natural or thicker than usual, as if they had participated, as regarded their thickness, in the increased nutrition

of their contents: the dura mater adhered closely to the cranium. A similar augmentation of the thickness of the cranial bones, but to a greater degree than I have remarked it, has been recorded by M. SCOUTETTEN, who met with it in a girl five years of age, who died of abdominal disease, and who had never complained of any disorder of the head, or of disturbance of the mental faculties, which were those common to children at her age.

92. *Rickety hypertrophy of the brain* is more frequent. It commences soon after birth, and often attains a great extent. OTTO supposes that brains which have been much expanded by dropsy in youth, become subsequently, in rare instances, cured by increased deposition of cerebral matter; and thus retain their size and weight. The distension of the cerebral substance by the accumulation of fluid in the ventricles, cannot be comprehended under hypertrophy of the organ.

93. M. ANDRAL (*Anat. Path. t. ii. p. 776.*) says, that, although hypertrophy of the brain is usually general, and extends to the whole of both hemispheres, it is sometimes also partial: thus he has seen the *thalamus opticus* of one side of its natural dimensions, whilst that of the opposite side was one fourth larger. This extraordinary development of the thalamus of one side was not attended with any particular symptom during the patient's life. OTTO refers to a number of cases of hypertrophy confined to a single part of the brain, chiefly to the *thalami* and the *corpora quadrigemina*. I am not aware that any well authenticated cases of marked hypertrophy of the *cerebellum* are upon record. The *spinal chord*, however, is not infrequently subjected to this change.

94. Morbid enlargement of the *pineal gland* has been observed by DRELLINCOURT, MORGAGNI, LIEUTAUD, DESPORTES, SOEMMERING, ANGELI, GREYING, MECKEL, and BLANE. The *pituitary gland* has also been found enlarged, inflamed, and otherwise changed, by GREYING, BAILLIE, CHAUSSIER, OPPERT, WARD, RULLIER, DE HAEN, RAYER, NEUMANN, ABERCROMBIE, OTTO, the WENZELS, and MECKEL.

95. *C. Imperfect development and atrophy of the brain*,—*Agenésie cerebrale* (CAZAUVEILLI),—is met with in every degree, from a slight diminution of the usual bulk of the whole organ, or of any of its parts, to their almost entire disappearance. Atrophy, although occurring in all situations of the cerebro-spinal axis, is most frequently observed in those which are the last formed: thus the spinal chord is formed before the brain, and atrophy of it is much rarer than that of the encephalon. Of the brain, the convolutions are the last developed, and they are most frequently atrophied. It should, however, be noticed, that the majority of those cases which are denominated atrophy of the brain by ANDRAL, and other French pathologists, are, strictly speaking, imperfect or arrested development of the organ. The hemispheres are most frequently the seat of atrophy and imperfect development; and they may be thus affected, either partially, or altogether. Imperfect growth of particular lobes, especially the anterior, is common in idiots, and may exist even although the cranium is well formed, the void being filled up with water, the congenital effusion of which is the probable cause of the arrest of development. When the hemispheres are par-

tially affected, the lesion is most commonly observed in the convolutions.

96. *a. Atrophy of the convolutions.*—These parts are sometimes only smaller and less numerous than usual, either in respect of one or both hemispheres, or in a portion of a hemisphere merely; and they may be altogether wanting in one, or in both. M. JADELOT lately found the hemispheres of the brain of an idiotic child, aged six years, without convolutions, and consisting of an uniform layer of medullary substance covered by a thin coat of cineritious matter.

97. *b.* Sometimes the greater part of the hemispheres of the brain, especially their superior portions, from the vault of the ventricles upwards, are found in a state of atrophy, or altogether wanting. Most of the cases of this description which have been adduced by the French pathologists, as well as the case of JADELOT, are merely instances of imperfect development of the part. Sometimes this portion of the encephalon is replaced by a sac containing a serous fluid, having no communication with the ventricles. In other cases, no such body replaces the deficient hemispheres; but the different parts of the anterior and superior aspect of the ventricles, as the thalami optici, corpora striata, &c., may be seen through the membranes, no substance intervening between them and those portions of the floors of the ventricles. These occurrences are, however, not cases of atrophy, but of arrest of the formative process as respects the hemispheres of the brain. Cases of diminished size merely, of one or both hemispheres, are more common than those now instanced; and are generally to be considered as being congenital, or, at least, the result of a diminished nutrition of the part in the process of the growth of the organs. Instances of extreme smallness, or an entire absence of a part of the hemisphere, are most frequently met with in its posterior or anterior lobes: either of which may be altogether wanting, in one or both sides of the brain. Diminished size of the anterior or posterior lobes are a much more frequent occurrence than their entire absence.

98. *c.* The thalami optici, and corpora striata, may be also much diminished in volume, either singly or together. The diminution may proceed from a defect either of the grey matter, or of the white substance; and from this cause of diminished bulk, the accompanying symptoms will derive their chief characters. Not only may those bodies be simply diminished in volume, they may be even altogether wanting, either being replaced by a serous cyst, or having no other body as a substitute: in the former case, the hemisphere of that side may be, or not, also entirely wanting; in the latter it is always absent, and, from the cerebral peduncles, nothing more is found than a few scattered fibres, which are spread out into a membranous tissue, resembling that which, at the earliest epochs of foetal existence, forms the rudiments of the hemispheres. It is evident, that in such cases, the white central portions of the brain being absent, and both sides of the cerebrum being thus circumstanced, there can scarcely be said to be any brain in existence. This, however, does not prevent the other parts contained within the cranium, as the mesocephalon, cerebellum, &c., from being fully formed.

99. *d.* The central white parts of the brain

may be imperfectly developed, even when no alteration is remarked in the hemispheres. In some such cases the corpus callosum is so small as to form merely a thin membrane. REIL remarked its entire absence in a female idiot, who died at thirty: the two hemispheres communicated only through the medium of the anterior and posterior commissures. It is remarkable, that when the cerebral lobes are wanting, two small masses of nervous substance, whence the olfactory nerves arise, are sometimes found in the anterior part of the cranium; thus displaying in man, in the morbid state, the independent existence of the olfactory lobes, naturally shown in animals.

100. It will be seen from the above, that all the parts of the brain may present a state of imperfect development to a greater or less extent; that either of them may be entirely wanting, while the others remain; and that all of them may be absent, so that there exists no brain: a circumstance not infrequently observed in foetuses, and evidently owing to the process of development having been suddenly arrested.

101. But not only may the brain be in part, or entirely, deficient at birth; it may be also remarkably small at advanced age, particularly in idiots. It may be generally, but more frequently only locally, diminished by external pressure, as in meningeal hydrocephalus. Although the brain, as well as the other parts of the nervous system, wastes so little in general consumption, it is, however, somewhat diminished, although rarely, in the course of certain diseases: SAVARIES states, that he has found it atrophied in yellow fever. HORN remarked a similar state in diabetes; and OTTO, after venereal excesses. Atrophy is, however, more frequently observed in particular parts of the brain. The lateral lobes of the cerebellum have been occasionally found atrophied. M. HUTIN observed the medullary centre of the cerebellum reduced one third of its natural size. MORGAGNI, WENZEL, and BIERNAYER have described atrophy of the corpora striata. The optic beds have been found greatly reduced in size after blindness, by SOEMMERING, MICHAELIS, RUDOLPHI, &c.; and in idiots, by OTTO, RAMSAY, and ROMBERG. The quadrigeminal bodies and the tubercles of the brain, have likewise been severally found atrophied. The pressure occasioned by tumours, collections of lymph, pus, or blood, or even dropsy of the ventricles, gives rise to atrophy, interstitial absorption, or destruction of particular parts of the brain. Impaired supply of blood owing to diseased arteries, causes both atrophy and softening. The want of exercise of the functions of the nervous system also occasions atrophy, by diminishing nutrition, as an unexercised muscle soon wastes. Thus, the wasting of the brain so generally observed in idiots, may be the effect and not the cause of idiocy. The pineal gland, and the pituitary gland or appendage of the brain, have both been seen remarkably atrophied, particularly the latter. According to OTTO, this change has been most frequently remarked in idiots, and in hydrocephalic cases.

102. *v. INDURATION, OR HARDENING OF THE BRAIN.*—*Sclerencephalia* (CRAIGIE).—The cerebro-spinal axis sometimes presents, either throughout its extent, or in particular parts, a remarkable increase of consistence. This increase varies in grade. In its first degree, it is nearly of the con-

sistence of a brain which has been kept some time in dilute nitric acid. The *second degree* of increased hardness resembles the consistence of cheese. In this state, the cerebral substance, when exposed to the action of fire, instead of swelling up, without emitting any marked odour, and leaving a brownish light residue, assumes a horny hardness, emits a strong heavy smell, and leaves a compact blackish residue. Nitrous acid also imparts to it a horny hardness,—circumstances evincing a great increase of the albuminous constituent of the structure. The *third degree* of hardening equals the firmness of wax, frequently also conjoined with elasticity, so that the indurated portion resembles fibro-cartilage.

103. *a.* The *first* grade of induration may affect the whole or the greater part of the cerebro-spinal axis. The two greater degrees of this change are commonly of more or less limited extent. *General hardening* of the brain is usually attended with augmented vascularity, numerous drops of blood becoming effused when the cerebral structure is incised. This increased vascularity, although general, is not constant; for, in some few instances, little or no injection of the capillaries is observed, the brain being rather exsanguineous than vascular. Even in the general induration of the brain, the hardening is not equal throughout every part. It is least remarkable in the cortical structure and convolutions; and more manifest in the white, particularly the central medullary parts than in the grey substance.

104. *b.* *Partial induration* of the brain is most frequently found in its central parts, and sometimes in the convolutions. M. ANDRAL has observed it in this latter situation, at as early an age as three years, which is extremely unusual. Sometimes the convolutions of the convexity of the hemispheres are unaltered, whilst those of the base are hardened; occasionally in such cases, especially when the induration is considerable, the cortical can scarcely be distinguished from the medullary structure. In a case recorded by LALLEMAND, the induration was limited to a circumscribed portion of cortical substance, and under it, the medullary texture was manifestly softened. M. PINEL found, in one of the hemispheres of a female who had died in a state of idiocy, a portion of the medullary structure extremely hardened; and, in the same individual, there existed, in the whole posterior and inferior border of the cerebellum, an induration of a fibro-cartilaginous description. The hardened portion was yellowish, elastic, resembling a piece of whitish yellow leather. Mr. PAYEN found, in a girl six years of age, near the posterior third portion of the left hemisphere of the brain, a depression, owing to hardening of one of the convolutions, which seemed externally as if it were shrivelled. It was rose-coloured on its surface, slightly yellowish in its substance, and almost concealed from view by two convolutions, which were healthy. The membranes covering this hardened convolution were white and thickened. Hardening was here joined to diminution of volume; or, perhaps, the disease of this portion of the brain was congenital, and, whilst the growth of the rest of the organ had proceeded, the development of this was interrupted. The intelligence of this child was well advanced; but she had, from birth, a contraction of the right wrist

and foot, with slight atrophy, and incomplete hemiplegia of this side. Similar cases of hardening of portions of the lobes of the brain are described by MONRO, LALLEMAND, and HUTCHINSON. In a case recorded by JOEGER, the induration was limited to the parietes of the posterior cornua of both lateral ventricles, and amounted almost to that of cartilage. BERGMAN found both optic beds hardened in a paralytic and squinting girl: and CASTELLIER and ANDERSON observed excessive hardening of the lobes of the cerebellum. Partial induration of the nervous centres frequently co-exist with other lesions of those organs, especially around old sanguineous effusions and morbid productions formed in the cerebral substance: they are also occasionally found accompanying the usual results of chronic inflammation of the membranes; these being firmly agglutinated together, to an extent of surface more or less considerable, and closely adherent to a subjacent hardened portion of brain. (PORTAL, *Anatomie Méd.* t. iv. p. 91.)

105. *Cause of hardening of the brain.*—The *first* degree of induration has been frequently found in persons who have died of fevers, generally of an ataxic or typhoid type, and in maniacs. M. ANDRAL observed it in two patients afflicted with convulsions from working in lead. MM. GAUDIT (*Récherches sur l'Endurcissement gen. de l'Encéph. comme une des Causes des Fièvres Ataxiques.* Paris, 1825.) and BOUILLAUD (*Archives Génér.* t. iii. p. 477.) consider it as the consequence of acute inflammatory action of the brain and its membranes, they having found it in persons who have died of encephalitis occurring either primarily, or as a complication in fevers; and M. ANDRAL (*Anat. Path.* t. ii. p. 810.) seems to coincide with this opinion. RUDOLPH observed it in thirty cases of typhus: and OTTO found, during the epidemic typhus of 1809 and 1812–13, hardening of the brain frequent in those who died within the first week; and softening in many who died at a later period. But, in these cases, granting the induration to have been the consequence of the disease which destroyed life, it must have taken place in the short space of a very few days; whereas, I am much more inclined to impute it to inflammatory action of a lower grade and of a much slower progress. M. BROUSSAIS regards it as the result of meningo-encephalic inflammation, of a sub-acute or chronic nature. As being generally found in connection with increased vascularity of the substance of the organ, and with this and other signs of inflammatory action of the membranes, the relation of this change to inflammation seems established; but I am inclined to adopt the inference of Dr. CRAIGIE, in respect of the opinions of MM. GUARDET and BOUILLAUD, that, in those cases in which they observed this lesion, it had existed previous to the acute disease which occasioned death.

106. Induration of the brain has been long familiar to pathologists, in relation to mental derangement. The writings of LITRE, GIOFFROY, BOERHAAVE, LANCISI, MORGAGNI (*Epist. Anat. Méd.* viii. 4—18.), J. F. MECKEL (*Mém. de l'Acad. Roy. de Berlin*, t. vii. p. 306.), LIEUTAUD, SANTORINI, GREYING (*Ludwig's Advers. Med.-Pract.* t. ii. pars 3. p. 533.), PORTAL, MARSHALL (*Morbid Anat. of the Brain, &c.* Lond. 1815.), HASLAM (*Observ. on Madness and Melancholy.* Lond. 1809.), SERRES (*Ann. Médico-*

Chirurg. Paris, 1819.), LALLEMAND (*Récherches Anat. Path.* let. ii.), LERMIER, BOUILLAUD (*Traité Clinique de l'Encéphalite.* Paris, 1825.), PINEL, jun. (*Rév. Méd.* t. vi.), FOVILLE, and PINEL-GRANDCHAMP, furnish numerous instances of it, thus related: and, from the history of the cases, as well as the generally augmented vascularity of the membranes and of the indurated brain itself, I infer that it is a consequence of chronic inflammatory action, conjoined with some change in the nutrition of the cerebral substance; and that it proceeds from a less intense and more chronic state of the vascular action than that which occasions softening, or pulpy destruction of the cerebral texture. That such is the case is proved, not only by my own experience, but also by the observations of the authors enumerated above; for, in the majority of those cases, even when presenting the appearances and consequences of cephalo-meningeal congestion and inflammation, the symptoms of cerebral disease were of much longer duration than those depending upon morbid softening of the organ.

107. It has already been stated, that induration of the cerebral substances, amounting to either the *second* or the *third* degree, is generally circumscribed in extent. Whatever doubts may be entertained of the *first* degree of hardening being the result of chronic rather than of acute disease, there can be no doubt of the second and third being always a chronic affection — perhaps, of a still more chronic state of capillary action than that giving rise to the first form of increased hardness; the morbid action, affecting in the former cases a portion of the brain only, may be compatible with a longer duration of life, and hence give rise to ulterior or more advanced stages of change than those presented when the whole organ is affected, and all its functions and energies thereby involved. That this change is one of the consequences of chronic irritation, or inflammatory action, may be conceded as well as the supposition entertained by ANDRAL and CRAIGIE, that the morbid irritation is connected with a perversion of the nutritive action. Indeed, the numerous cases detailed by PORTAL, SERRES, LALLEMAND, BOUILLAUD, PINEL, and others, furnish satisfactory evidence, both in the symptoms during life, and in the co-existent lesions in the membranes and other parts of the brain, of the existence of a chronic inflammatory action, or of a state of irritative erythsm of its capillaries. But to say that this state is in such cases accompanied by a perversion of its nutritive actions, is ascribing to it what always is an attendant upon inflammatory action, of whatever grade, or in whatever texture it may be seated. It should, however, be mentioned, that M. LALLEMAND considers partial induration to occur occasionally as a favourable termination of morbid softening of the brain; but this is a mere supposition.

108. As to the *phenomena* to which induration of the brain gives rise, every practical man must feel considerable interest. The *first* and more *general* induration of the brain generally occasions loss of memory, confusion of thought, and derangement of the mental manifestations — causing insanity without lucid intervals. When the induration is advanced in degree, or considerable as to its extent, or both, and especially when its long duration has been indicated by continued

mental derangement, a complete obliteration of the mental faculties, or fatuity, is frequently its attendant towards the last periods of life, and may therefore be considered as the consequence of the most advanced degrees of this lesion. The signs of *partial induration* of the brain, in any of the grades to which I have referred, will vary according to the extent and seat of the lesion. They consist chiefly of a progressive defect of memory, inattention, or an inability to pursue a long train of ideas, indifference to momentary impressions, and to present or future occurrences, difficulty of articulation, derangement of ideas, with partial or total loss of the affections, appetites, and desires; and ultimately increased loss of speech, palsy, convulsions, or want of power over the muscles, fatuity, general or partial wasting, and death.

109. LALLEMAND found, in a patient who had complained of fixed pain of the forehead, palsy of the face, and confusion of memory, the membranes firmly matted together, for the extent of a thirty sous piece, at the anterior extremity of the left hemisphere; and the subjacent cerebral substance hardened to a scirrhous or cartilaginous firmness, and adhering closely to the membranes. BOUILLAUD states the case of a man, aged sixty-eight, who, after symptoms of cerebral disease, had impaired memory, headach, difficulty of expressing his ideas, followed by muscular weakness, and convulsions: the cerebral substance was found injected, and induration was seen "passing from the striated body of the left hemisphere, through the nucleus, at the upper region of which it formed a cavity with hard yellow walls: a similar hardened portion also existed in the posterior lobe." According to M. PINEL, induration confined to the brain causes fatuity, with more or less of palsy; but, if it extend to the annular protuberance, the crura cerebri, the corpora olivaria, or chord itself, epilepsy, followed by palsy, and death by marasmus, are generally superadded. In these advanced degrees of hardening, which are sometimes attended with a shrunk, depressed, and condensed appearance, — a species of atrophic hardening of the part, — there are usually remarked palsy and idiocy, which are either congenital, or occurring subsequently to birth.

110. vi. MORBID GROWTHS. — *Tumours of the brain.* — Tumours of various kinds have been found to originate in the substance of the brain; but as Dr. CRAIGIE (*Anat.* p. 447.) has observed, they have not been distinguished with sufficient precision by authors, from those which, originating in the membranes, affect the brain only secondarily. The *first* form of tumour which he has described, and denominated "*cerebral tumour*," entirely agrees with those partial indurations already considered; differing from them in no respect, but in the extreme degree of firmness it presents, which is similar to the second and third (the latter particularly) degrees of hardening, arising in the manner I have endeavoured to explain (§ 104.), and affecting all parts of the nervous masses, — the cerebellum and medullary chord, as well as the various parts of the brain itself. (See HARDENING, &c.)

111. A. *Tubercular secretion.* — *Tyroma* (CRAIGIE). — Tubercles of the brain have been described in recent times with much accuracy by GENDRIN, LÉVEILLÉ, OLLIVIER, ABERCROMBIE,

ANDRAL, and CRAIGIE. They are formed of a white, or pale yellow, opaque, firm, cheese-like, sometimes granular and friable substance, consisting of a large proportion of albuminous matter, and varying in size, from that of a millet-seed to the bulk of a hen's egg. This substance is deposited in various forms in the brain, but usually as follows: — 1st, One, two, or more, homogeneous, distinct masses of considerable size; 2d, Several, or many, separate, minute, spherical, or spheroidal masses. Cases of the first form of tubercular formations are to be found in the writings of MANGÉT, ROCHOUX (*Récherches sur l'Apoplexie*, p. 151.), POWELL (*Trans. of Coll. of Phys.* vol. v. p. 222.), BLANE (*Trans. of a Society, &c.* vol. ii.) BAILLIE (*Fasc. of Eng.* No. 10. plate vii.), COINDET (*Mém. sur l'Hydrocéph.* p. 106.), BOUILLAUD (*Traité, &c.* p. 161.), ABERCROMBIE (*Dis. of the Brain, &c.* p. 428.); CHAMBERS (*Med. and Phys. Journ.* vol. lv. 1826, p. 5.), PIEDAGNEL (*Journ. de Phys.* t. iii. p. 247.), BERARD (*Ibid.* t. v. p. 17.), and HOOPER (*Morbid Anat. of the Brain*, p. xi. and xii. fig. 1.). Tubercles of this class vary in number from one to five or six, and in size from that of a pea to the bulk of a hen's egg. In form they closely resemble tubercles in other parts of the body. According to LÉVEILLÉ, they are often of an unequal surface, so as to appear lobulated, particularly when they are very large. If only one or two are present, their size is generally considerable. M. ANDRAL mentions their existence in the cerebellum, of so large a volume as to destroy nearly the whole of one of its hemispheres. Even when of this bulk, they consist of the opaque, cheese-like substance already described, and are always destitute of vessels, or any trace of organic structure. They are albuminous, friable, and generally surrounded by a cyst. MM. GENDRIN and LÉVEILLÉ are of opinion that they always have cysts, but of variable thickness, which are sometimes remarkably thin, at other times, especially in old tubercles, thick and fibrous. The cyst adheres externally to the surrounding cerebral structure; and its internal surface sends off delicate filaments, which traverse the continued tubercular matter, and, in the large and old tubercles with thick cysts, seem like small fibres or partitions passing between the lobules of the contained substance, which is disposed in cellules formed by these filaments. In some large and old tubercles, the cyst is fibrous, cartilaginous, or even osseous (GENDRIN), and is sometimes partially separated from the surrounding cerebral structure by a minute quantity of serous fluid. In proportion as the tubercle softens, the cyst becomes more apparent.

112. The surrounding cerebral substance is often perfectly natural, and sometimes variously altered; — occasionally inflamed, or softened, or atrophied, or even destroyed, especially when the tubercles are very large. Upon these lesions, the symptoms during life are often chiefly dependent. Very frequently, especially in children, tubercles varying as to number and size may exist in the brain, without occasioning any symptoms sufficient to lead to the suspicion of cerebral disease: but this seems to be the case only when the nervous substance around them has been but little changed from the healthy state. When nervous symptoms have appeared without such

change, they have generally assumed an intermittent character.

113. It is very probable that tubercles are formed in the brain, as elsewhere, at first in a fluid state; and that they afterwards either undergo a slow coagulation, or have their aqueous portions partly absorbed, the albuminous and other more solid constituents forming the tubercular substance. M. BOUILLAUD believes that they are the product of an inflammatory process; and the tendency of inflammation to produce an albuminous secretion certainly countenances this opinion. Whatever may be the origin, they appear to experience in the brain a similar softening to that which they undergo when formed in other organs. When this is advanced to more or less partial fluidity, tubercles may be mistaken for other formations; and when amounting to liquefaction, the tubercular production can, with difficulty, be distinguished from a small encysted abscess. (See art. TUBERCLES.)

114. The second form in which tubercular productions are found in the brain, is that of spheroidal bodies, disseminated through its substance. Professor REIL (*Memorab. Clínica*, t. ii. fas. iii. No. 2. p. 39.) describes them, in a case which occurred to him, to have consisted of about two hundred spheroidal bodies lodged in the grey matter of the brain and cerebellum. They were a little firmer than the brain itself, mostly of a pale yellow, some of a pale blue, of the size of a lentil or pea, and consisting of an adipose-like substance. From some, which were marked in the centre with a dark point, and seemed covered by a thin cyst, a slight incision discharged a matter-like vermicelli. These bodies were confined entirely to the cortical substance of the brain, chiefly near the deep anfractuosités, and but very few were in the prominent parts of the convolutions. They were most numerous in the superior aspect of the hemispheres, less so in the cerebellum, and least numerous in the base of the cerebrum. The pia mater was remarkably injected with blood, and the ventricles contained very much fluid. This patient had never complained of pain in his head, although long afflicted with scrofulous sores, until eight days previous to death. In a case recorded by M. CHOMÉL (*Nouv. Journ. de Méd.* t. i. p. 191.), similar bodies were found disseminated through the brain of a woman aged thirty, who died with symptoms of cerebral disease. Two such productions were also found in the cerebellum, and one in the spinal chord. Cases similar to the above have likewise been recorded by other writers. Tubercles, even in the form now being considered, are seldom or ever found in greater number than in the case just quoted from REIL; and, as GENDRIN has remarked, they are never found in the brain in so very great numbers as in the lungs; nor, in my opinion, do they assume, in the cerebral structure, the agglomerated form, in which they are so often met with in other viscera, and in the lungs especially.

115. Tubercles are often met with in the brains of children, and those especially of a strumous diathesis, and upwards of one or two years of age. They occur most frequently from this age to puberty; after which they are rarely met with, even in scrofulous and phthisical subjects, where tubercles exist not only in the lungs, but

also in other organs. They are most common in the hemispheres of the brain, and there occupy indifferently either the cortical or the medullary texture: sometimes they appear, as it were, placed between both. In some cases in which they have been found in the more exterior layer of the cineritious structure, they seem not to have been originally formed in it, but to have sprung from the internal surface of the pia mater, and to have pressed inwards the cerebral tissue as they increased in size, forming, as it were, a superficial cavity in it, without any intimate union with it beyond that of close contact. The parts of the brain, after the hemispheres, where tubercles are most commonly found, are, according to M. ANDRAL, the cerebellum, the mesocephalon, the medulla oblongata, various parts of the spinal chord, the peduncles of the cerebrum and cerebellum, the thalami optici, corpora striata, the commissures of the thalami, and pituitary body. According to the order of frequency here indicated, it will be observed, that those parts of the cerebro-spinal axis which are most frequently the seats of inflammation, softening, or hæmorrhage, are not those which are oftenest the seat of tubercles.

116. *B. Adipose tumour* (WENZEL).—*Fatty productions* (ANDRAL).—*Lardaceous degeneration* (HEBREART, *Annuaire Méd.-Chirurg.* Paris, 1829. p. 579.).—*Ceroma* (CRAIGIE).—This morbid formation has been noticed, under the above designations, by the authors whose names are respectively noticed, and also by RUDOLPH, BRAUN, CRUVEILHIER, MERAT, LEPRESTRE (*Archives Génér. de Méd.* t. xviii. p. 19.), and DALMAS (*Journ. Hebdom. de Méd.* t. i. p. 332.). BORELLI states that he has found, behind the upper part of the medulla oblongata, a fatty, homogeneous, reddish, or rose-coloured substance, the size of a nut, apparently traversed by reddish lines, and contained within a thin envelope. A similar tumour, though smaller, was found in the left cerebral hemisphere. Amongst the great number of brains examined by the WENZELS, only two presented this change; which they describe as having been smooth, of a yellow colour, and consisting of a solid, adipose, ash-coloured substance; and, although found near the exterior surface of the hemisphere, penetrating deep into the substance of the organ.

117. According to M. HEBREART, this disease is not so rare as the WENZELS lead us to suppose. He had met with four cases of it; two in which the tumour was seated in the brain, and two in the cerebellum. "In the first of the former, a distinct tumour, consisting of matter of a yellow colour, and lard-like consistence, the size of a nut, in the anterior part of the anterior lobe of the right hemisphere, gave rise to idiocy. In the second, a square inch of the posterior lobe of the left hemisphere was converted into a yellowish pulpy matter, which was separated from the contiguous sound brain by hardened cerebral substance. This, in a man aged forty, caused epileptic paroxysms, occurring once or twice a month, which at last proved fatal, by causing asphyxia. In the first of the cerebral cases, in a young man who had been idiotic for six years, the cerebral substance, forming the walls of the fourth ventricle, had been converted into a yellowish lardaceous matter. In the second, that of an

incurable maniac, a space, six lines in diameter, of the lower part of the right hemisphere of the cerebellum, had become hard, yellowish, and lardaceous, both in the grey substance, and also in the white." The membranes also participated in this change. M. HEBREART considers that this lesion may occur in two forms,—1st, As a degeneration of the cerebral structure into a matter of a yellowish colour and lardaceous consistence; and, 2d, In the shape of a distinct tumour situated in the cerebral substance.

118. Closely allied to the above, although materially different in some respects, yet still more strictly deserving the term adipose, are the tumours described by LEPRESTRE and DALMAS. M. LEPRESTRE found, in the left side of the mesocephalon of an adult subject, a large tumour, with a brilliant lobulated surface, consisting of concentric layers, united by means of fine cellular tissue, but without any trace of blood-vessels. It was denser in its structure than the brain, and closely resembled a mass of adipocire. This resemblance is remarkable, inasmuch as MM. BARRUEL and GMELIN have demonstrated, in the healthy human brain, a certain quantity of fatty matter and cholesterine. The tumour found by M. DALMAS nearly resembled the foregoing. It was situated in the base of the brain, and was as large as a hen's egg. It rose upwards into the third ventricle, separated the parts which contribute to the formation of this cavity, and disappeared in the medullary substance of the striated bodies, the thalami optici, the anterior commissure, &c. Its superior surface closely resembled spermaceti. Its inferior surface was transparent, polished, and studded with a number of pearl-like granulations, from a line to a line and a half in diameter, which were, like the whole of the mass, perfectly homogeneous, and devoid of every trace of organisation. When analysed by M. BARRUEL, this tumour was found to contain a very large portion of fatty matter, and a substance which seemed to be cholesterine. The description of a similar tumour is recorded in the first volume of the *Journal Clinique des Hôpitaux*. OTRO also found a fatty tumour, which contained hair, protruding through an aperture in the hemisphere into the ventricle, its cyst shining like mother-of-pearl.

119. *C. Flesh-like tumour*.—*Adenoidea* (CRAIGIE).—This production has been described by the vague names of scirrhus and serofulous tumour; but it cannot be admitted to possess unequivocal characters of either. It is generally stated to be similar to a mass of flesh, or an enlarged absorbent gland. Its colour is light pink, or pale flesh-colour; its firmness is considerable; and, in some instances, it is compared to the kidney. Cases of this description of lesion may be found in the writings of PLATER (*Obscr. l. i. p. 13.*), T. BONET (*Sepulchretum*, t. i. p. 283.), RHODIUS (*Cent. Obs. l. No. 55.*), J. J. WAGNER (*Miscell. Curios. Dec. II. Ann. 10.*), J. G. ZINN (*Comment. Soc. Reg. Scient. Gott. t. ii. 1752.*), J. J. HUBER (*Nova Acta Physico-Medico Acad. Cæs. Leop. Cur. t. iii. p. 533.*); et *Comment. de Rebus in Scient. Nat. t. xviii. p. 335.*), HALLER (*Opusc. Path. Obs. i.*), J. E. GREDDING (*Ludwig's Advers. Med. Pract. t. ii. part. ii. p. 492.*), H. EARLE (*Med. Chirurg. Trans. vol. iii. p. 59.*), POWELL (*Trans. of Coll. of Phys. vol. v. p. 241.*), &c. Most

of those cases appear to have occurred in strumous habits; and, besides signs of glandular disease, many of them were affected with palsy, apoplexy, or mental derangement; and others with convulsions and epilepsy, shortly before death. M. ANDRAL (*Anat. Patholog.* t. ii. p. 848.) mentions his having found, in the middle of one of the hemispheres of the brain of a person who had died of apoplexy, a fleshy fibrous tumour of the size of a walnut.

120. *D. Fibro-cartilaginous tumour*,—*Scirrhus, Chondroma* (HOOPER and CRAIGIE),—is probably, in its slighter grades of change, merely an advanced state of the third variety of partial induration of the brain (§ 103.). It is distinguished from the surrounding cerebral substance by its great firmness; its irregular and lobulated form; its yellowish, hard, and fibrous structure; and, in its advanced stages, by the presence of a semi-fluid, gelatinous matter, occasionally tinged with blood, contained in small cavities, disseminated through it; and by a tendency to softening; death, however, generally taking place before complete softening, or cancerous ulceration, has supervened. This tumour is not often met with in the substance of the brain, and very seldom as a primary affection. It seems to consist of a change in the structure of the part affected, rather than of a deposition of adventitious matter; and it is not enveloped by any cyst; but gradually disappears in the surrounding substance, which is sometimes softened. All the cases which have been recorded of scirrhus of the brain, are not in every respect similar to the above description, but an approximation to it merely; some, according to the loose accounts given of them, being intermediate between this and the cartilaginous conditions. The best illustrations of this form of tumour have been furnished by CRUVEILLIER (*Anat. Pathol.* t. ii. p. 80.), ROSTAN (*Récherches sur le Ramollissement du Cerveau*, &c. 1re ed. p. 80.), ANDRAL (*Journ. de Physiol.* t. ii. p. 105.), BOUILLAUD (*Traité Clinique de l'Encéphalite*, &c. 1825.), LERMINIER (*Ann. Méd.-Chirurg.* 1819. p. 225.), MONRO (*Morb. Anat. of the Brain*, p. 55.), WADE (*Medic. and Phys. Journ.* vol. iv. p. 369.), BAYLE (*Réch. sur la Phthisie Pulmon.* &c. p. 305.), and COPLAND HUTCHISON (*Trans. of Med. and Chir. Soc.* vol. ii. and iv.). All these cases were characterised by acute pain in the head, stupor, palsy, idiotcy, convulsive movements, and, at last, insensibility, coma, or complete apoplexy, and death; or by one or more of these symptoms; and several of them seemed to originate in external injury received at a more or less remote period.

121. *E. Bony tumours and calcareous concretions*,—*Osteoma* (HOOPER),—are rarely observed in the substance of the brain. Cases have, however, been furnished of their formation, in more or less considerable masses,—near the right ventricle, in an idiot, by KERKINGIUS (*Obs. Anat.* p. 135.); in the corpus striatum, by DEIDIER (*Des Tumeurs*, &c. p. 351.), and KENTMANN (*De Calc. in Hominib.* Tig. 1536.); in one of the corpora quadrigemina, by TYSON (*Phil. Trans.* No. 228.); in the union of the optic nerves, by BLEGNY (*Zodiac. Gall.* Obs. xiv. p. 81.); where they were attended by violent pain in the occiput, by BOYEA (*Cruveilhier's Anat. Path.* t. ii. p. 84.); in the cerebellum, by LITTE (*Mém. de l'Acad. de Paris*, 1705, p. 55.); in the cerebellum of an epileptic,

by LIEUTAUD (*Hist. Anat. Méd.* l. iii. Obs. 179.); in the pons varolii, by METZGER (*Obs. Anat. Reg.* 1792, p. 3.); in the optic beds, by CALDANI (*Opusc. Anat. Path.* 1803, p. 51.); in one hemisphere of an epileptic, by OTTO (*Comp. Anat. Path.* p. 415.); in the cerebellic peduncles and protuberance of an idiot, by HOME (*Phil. Trans.* 1814.); in the left hemisphere, by ANDRAL (*Journ. de Physiol.* t. ii. p. 110.); in the cerebellum, with violent pain at a determinate part of the occiput, by NASSE (*Abercrombie on Dis. of the Brain*, p. 426.); in the centre of the medullary substance of the anterior lobe, with pulpy destruction of the surrounding part in one case, and in the cerebellum in another, by Dr. HOOPER (*Morb. Anat. of the Brain*, p. 39.). Besides these, other instances are referred to in the *Repertorium of PLOUQUET*, and the *Compendium of OTTO*. In more numerous cases, the chalky, calcareous, or bony matter, is disseminated like sand in a diseased portion of brain, and can be detected only by squeezing or rubbing the part between the fingers. In some cases the bony matter appears like minute spiculæ, or particles; and Dr. HOOPER states that he has found each of them attached to a filamentous vessel.

122. *Sabulous concretions* are so constantly found in the *pineal gland*, or its peduncles, even of those whose cerebral functions were most healthy, that SOEMMERING conceived them to form a part of its natural structure in adults. But this part may be greatly enlarged, and contain calcareous matter to an excessive amount. A case of this description is given by MANGET (*Theat. Anat.* l. iv. c. ii. p. 309.) and SALZMANN (*De Gland. Pineal. Lapid. Arg.* 1733.).

123. *F. Hygromatous tumours, or cysts, containing a serous or albuminous fluid*,—*Hygroma* of HOOPER,—are not infrequently found in some part or other of the brain. Dr. HOOPER has described four varieties of these cysts:—*a.* That consisting of a *simple cell, or cavity*, containing a transparent, yellowish, or yellowish red, serous fluid. Their sides are somewhat harder than healthy brain, occasionally rough, and of a brownish hue internally, but mostly smooth and shining. They present no appearance of membrane lining the cell, nor of vascularity; are of the size of peas or nuts, and are most frequently met with near the external surface of the brain. They appear to be the remains of cavities formed by extravasated blood.—*b.* Another variety is a distinctly *encysted tumour*, consisting of a membranous cyst, or vesicle, filled with a serous fluid. This cyst is delicate, is formed of a single membrane, and is provided with vessels coming from the surrounding brain, and which may sometimes be seen ramified over it. The fluid which fills it is colourless and limpid. This variety varies from a very small size to that of a small orange. It is sometimes solitary; but occasionally two or more may be embedded close together.—*c.* Dr. HOOPER describes *two other varieties*, one of which is formed of a cyst, which is opaque in some parts, and transparent in others, and distended with a sero-albuminous fluid. The cyst is not apparently vascular, but is much thicker than the preceding; and its contents coagulate by heat:—*d.* The other is characterised by the remarkable thickness of its cyst, and the thick albuminous nature of its contents. It is generally found

embedded in the medullary substance of the brain.

124. *G. Hydatids.*—The existence of *true hydatids*,—both the *acephalocyst*, or headless hydatid, and the *cysticercus*, or bladder-tailed hydatid,—in the substance of the brain, has been doubted. Several cases of hydatids in this part have been adduced by authors; and instances have occurred to ANDRAL and CALMÉL (*Anat. Pathol.* t. ii. p. 779.), which they considered to belong to the latter of the above species of entozoa; but whether they actually were such, or some one of the cysts described above, rests upon the pathological reputation of these physicians. Those adduced by HOME, HEADINGTON, MORRAU, and ROSTAN, seem to have been merely varieties of *hygroma*. Dr. HOOPER never met with hydatids in this situation, in his numerous dissections. BRERA states that he has found them in the choroid plexus; and Dr. MONRO relates a case, where a cyst, which he considered as a true hydatid, was found in one of the ventricles. But their connection with the membranes of the brain (§ 31.) has already been shown.

125. *H. The Hæmatomatous tumour*,—the *Hæmatoma* of HOOPER,—is not common. It is mostly fungus, arising from a small base, separating the convolutions and cerebral substance about it, as it enlarges and rises towards the surface of the brain. It is soft to the touch; is elastic, and covered with a vascular and shaggy membranous tissue. When divided, its inner structure is vascular, mottled, of a whity brown, and, in some parts, of a bloody colour; and a humid substance adheres to the knife like cream. Interesting cases have been detailed by ROCNOUX (*Rech. sur l'Apoplexie*, Ob. 38. p. 149.), HOOPER (*Op. cit.* pl. x.), MONRO (*Op. cit.* p. 56.), and G. GREGORY (*Med. and Phys. Journ.* vol. liv. p. 462.), in which these tumours were, exteriorly, of a reddish or reddish brown colour, lobulated, and surrounded by pulpy destruction of the cerebral substance. In two of the patients, violent head-ach and epilepsy, and, in one, palsy, followed by coma, preceded dissolution. This tumour must not be confounded with the solid nodules of extravasated blood, often found after apoplectic seizures.

126. *I. Encephaloid or cerebriform tumours*,—*Medullary sarcoma*,—*Fungus hæmatoides*—*Cephaloma*, HOOPER.—These tumours are not frequent. Delineations of them have been given in Dr. BAILLIE's and Dr. HOOPER's illustrations. They occur chiefly in young subjects; and are encysted, soft, compressible, and spongy, resembling the grey cerebral substance, with a tinge of red, and of the consistence of the foetal brain. They are frequently divided into lobulated masses. When cut with a knife, the surface is smooth, and the knife is covered with an unctuous substance. I have met with one case in a boy of eleven years of age. M. BAYLE found it in the cerebellum of a middle-aged man. (*Rev. Méd. Avr.* 1824, p. 77.)

127. *K. The Melanoid tumour*,—*Melanosis*,—*Melanoma*, of HOOPER.—Melanosis has rarely been found in the brain. Dr. HOOPER has, however, observed it in a tuberculous form, both in the cineritious and medullary structure. These tumours were of a jet black colour, soft, distinctly circumscribed, and closely surrounded by healthy brain. Dr. H. has found them of all sizes,

from that of a mustard seed to that of a walnut. "They are so soft as to require a very sharp knife to cut them, which they soil. They are easily taken out of the brain with a forceps, and leave a clean cavity, without any cyst apparent to the naked eye; and if shaken in water, they colour it black, and a flocculent substance remains. In one instance, in which there were several of these tumours, some of them were of a blood or liver colour, and resembled hæmatoma (§ 125.); others were perfectly melanomatous; and several were of an intermediate colour,—a circumstance which is very much in favour of the hæmatoma and melanoma having an intimate connection, if they be not one and the same disease, modified by particular circumstances." (p. 41.)

128. All the tumours now described occasion alterations, generally of an inflammatory nature, with softening in the substance of the brain contiguous to them; and until those alterations have been in some measure produced, they often give rise to but little disturbance of the functions of the organ. However, when these changes become developed, the usual symptoms of *circumscribed inflammation of the substance of the brain* with softening; *epilepsy*; loss, or perversion of one or more of the mental faculties—amounting often to *insanity*; *idiocy*; *palsy*; *coma*, and *apoplexy*; are the usual effects. (See the Articles on these diseases.)

129. vii. RUPTURE OF THE BRAIN.—*Hernia cerebri*,—*Encephalocele*,—is occasionally met with. It consists of the protrusion externally of a portion of the brain through openings in the cranial bones. This lesion either may be *congenital*, or may arise *subsequently* to birth. In the former case it is generally connected with effusion of fluid in the ventricles. The protrusion of brain varies with the size of the aperture in the skull, and the quantity of effusion causing it. In some cases a large portion of the skull is wanting, and the protruding part of the brain has a wide base: in other cases, the opening in the cranium is small, and the protrusion is either very small, or attached to a narrow neck. OTTO states that, in every case which he has observed, the lesion was owing to effusion, and not to hypertrophy of the substance of the brain; and that the aperture arising from deficient development of the bones of the cranium was one of the consequences of the effusion. This agrees with my experience, and constitutes *hydrancephalocele* or watery rupture of the brain. In some cases large portions of the brain are protruded, in others but small. Frequently the protrusion consists only of the membranes forming *hydrancephalocele meningea*, and the water which they contain. OTTO describes this as a rare occurrence. I have met with several cases at the Infirmary for Children, and in unusual situations, namely, through clefts in the parietal bones. In rare cases of *hernia cerebri*, the water is found both within the ventricles and between the membranes.

130. Congenital rupture of the brain occurs most frequently on the back of the head, through the enlarged occipital foramen, and the cleft upper cervical vertebra, or through a cleft in the upper part of the occipital bone, or in the lambdoidal suture. It is not frequent at the top of the head, especially at the great fontanel; and OTTO says it is still more rare in the sides of the skull and

forehead, and the rarest of all in the orbits and sphenoidal sinuses. Two cases, however, of its occurrence at the sides of the skull have come before me. Rupture of the brain, occurring *after birth*, arises from the expansion of the brain by its own elasticity, or by increased determinations of blood, and its consequent detrusion through apertures naturally or artificially made in the cranium. I have met with cases, however, in which no protrusion of the brain had been observed after birth; and yet apertures, through which it might have occurred, were found in the middle or squamous parts of the bones, and must have been congenital. The inference is, in these cases, that a watery tumour of the brain had arrested the formation of the bone immediately over it, and that this tumour had subsequently disappeared, probably from the absorption of the aqueous effusion; but that the bone had not yet been formed in the situation where the ossific process had been interrupted.

131. viii. LACERATION.—The continuity of the brain may be destroyed by external violence, or injuries penetrating the cranium, either with or without loss of substance. Concussions also will *lacerate* the brain, without the skull being penetrated or even fractured. The substance of the organ, particularly the septum and fornix, may be torn by large collections of water in the ventricles. There is every reason to suppose that, when the solution of continuity is simple, adhesions will take place. When there is loss of substance, the injury can be repaired only by granulation. If the laceration be accompanied with the effusion of blood, so as to form a large coagulum, requiring to be absorbed, the reunion of the opposite sides of the lacerated brain is effected by means of a fine cellular tissue; permanent paralysis being the usual consequence. When the granulations of the lacerated brain protrude through the fractured skull, owing to their luxuriance, or rather to the elasticity of the brain; and when the protrusion proceeds from the distention arising from the fulness of its vessels, the morbid condition has been improperly called *fungus cerebri*, — improperly, inasmuch as the term *fungus* is applied to a malignant and constitutional malady.

132. ix. ECCHYMOSES, AND ALTERATIONS OF COLOUR.— Besides the lesions now described, there are others of a less remarkable kind, of which a brief notice may be taken. — *a.* The *cineritious substance* may be extremely pale, and even approximating to white; and it may also be of a very deep colour, and almost approaching to black, particularly in some cases of asphyxia and fevers, owing probably to the dark and imperfectly decarbonised state of the blood. The different layers composing this substance are sometimes also more than usually distinct, and separate easily from each other (M. FOVILLE and Dr. BRIGHT). In other cases they are very thin, as if in a great measure absorbed. This part of the cerebral substance likewise, in some instances, presents numerous *ecchymosed spots* of various sizes and depth of colour. — *b.* The *medullary structure* is also sometimes *ecchymosed*, particularly after concussion; and variously *marbled*, and presenting blotches of a pink, purplish, greyish, or of a greyish yellow. These changes seem to proceed from excessive injection of the minute capillaries of the organs, and probably from par-

tial extravasation of their contents, owing to over-distention, or a morbid state of the blood which had circulated in them shortly before death, and are most commonly observed after death from convulsions and malignant diseases.

133. As respects the *colour* of the brain generally, I may state that it is sometimes found unusually pale from deficiency of blood, in cases of anæmia and cachexia. But it is more commonly of a *deep* or *pink colour*, particularly in those who have died from apoplexy, strangulation, narcotic poisons, asphyxia; and in the insane, or those given to drunkenness. In some cases resulting from those diseases, or attended with cerebral congestion, dark red, *bluish*, or *purple-coloured spots*, or even streaks, have been found in both the cortical and medullary structures. In cases of inflammatory irritation, a reddish or pink hue is observed. A *red colour* is rarely met with, but more commonly a *pale rose tint*, unless effusion of blood have occurred. I may also state, at this place, that if, in severe diseases of the brain, the blood be decomposed, or if the colouring particles be secreted in various proportions, the brain will present different shades of colour, both in its cineritious and in its medullary substance: it will thus be either a pale or dusky yellow, an orange, a brown, greyish green, a slate colour, and even here and there soot-coloured. Occasionally, also, in different changes of texture, although even without these, a deposition of a *melanotic pigment* takes place, chiefly in the course of the larger vessels, independently of the melanoid tumour (§ 127.). OTTO never observed the brain generally tinged yellow in cases of jaundice, and doubts it having ever occurred, although STOLL says that he has seen it. I should add, that the above changes of colour are independent of marked softening or pulpy destruction of the cerebral substance.

BRAIN — ANÆMIA OF THE. — See § 132., and art. CONVULSIONS.

BRAIN — CEREBRAL PLETHORA. — *Determination of Blood to the Head.* CLASS. II. CLASS. I. ORDER (Author).

134. When the blood is determined in too great quantity to the brain, although the patient may not be altogether incapable of his usual avocations, yet much disorder may be present, which, if neglected, may lead to serious diseases, more especially to those which will be considered in the sequel of this article.

135. i. *Causes.*—The causes of general vascular plethora likewise occasion this affection. Those which are more peculiar to it, are inactivity of the secreting and excreting functions, mental exertion, retention of accustomed evacuations and discharges, full living, sedentary occupations, and want of exercise in the open air; organic diseases of the heart, particularly hypertrophy of the left ventricle, and those causes which are enumerated under the article APOPLEXY.

136. ii. *Symptoms.*—Cerebral plethora, and determination of blood to the head, differ in many respects from cerebral congestion, or *coup de sang* (§ 139.), but the symptoms accompanying them vary chiefly in degree. Where the disorder consists merely of plethora from local determination, somnolency, cephalalgia attended with scintillations, and objects appearing of a red colour, vertigo, noises in the ears, sometimes sleeplessness, moral and

physical excitation, intellectual activity; or, on the contrary, inactivity, inability of continued attention, stiffness, cramps, twitchings, &c. of the limbs; animation of the countenance and eyes, which are sometimes red or injected, with strong pulsation of the carotid and temporal arteries, full and somewhat frequent pulse, and slightly increased temperature about the head, are the usual symptoms.

137. iii. *Morbid appearances.*—This state of disorder never of itself occasions death; but, as it sometimes occurs in the advanced stages of fatal diseases, it has been observed to consist of increased vascularity in the brain and its membranes, without further organic change; but it is sometimes accompanied with a slight serous effusion into the ventricles and between the membranes, particularly towards the base of the brain. This effusion seldom amounts to more than may be present in the healthy state of the organ, the excess being probably rather a consequence of death than its antecedent.

138. iv. *Treatment.*—Cerebral plethora may generally be removed by avoiding the causes inducing it; by promoting the abdominal secretions and excretions by the usual means; by the affusion of cold water on the head, and the daily use of the shower-bath, or by sponging the head with cold lotions; by clothing the lower extremities warmly, and promoting the cutaneous perspiration; by regular daily exercise; by due attention to the quantity and quality of the food; and by changes of air in obstinate cases, and sea voyages.

BRAIN.—CONGESTION OF BLOOD IN THE.—

Coup de Sang.—*Cerebral Congestion.* CLASS. II. CLASS. I. ORDER (*Author*).

139. Congestion is an advanced as well as a modified state of cerebral plethora, and consists in too great an accumulation of blood in the vessels of the head, particularly in the venous capillaries and sinuses, occasioned either by too great a flux of this fluid to the brain, an exhausted tone of the capillaries and smaller vessels, or impeded return of it by the veins. This state of circulation is so important an organ as this is, necessarily occasions marked lesion, not only of the functions which it performs, but also of other functions throughout the system.

140. i. *Symptoms.*—Cerebral congestion is characterised by numbness, vertigo, noises in the ears, somnolency, brilliancy or watering of the eyes, cephalalgia, redness of the countenance, beating of the carotids and temporal arteries, loss of recollection, &c. These symptoms continue for some time in different degrees, sometimes disappearing, and after a while returning, accompanied with cramps, twitchings of the limbs, generally of both sides: at last the patient loses sense and voluntary motion, in a more or less sudden manner. But usually in the course of a few minutes, or, at furthest, some hours, the more urgent of these symptoms disappear; leaving, however, numbness of the limbs, which generally disappears in a short time, or in the course of one or two days.

141. In the more severe cases, and those which more nearly approach complete apoplexy, the attack is preceded by disorder of the stomach, or accompanied by nausea, or vomitings; and sometimes, during the loss of sense and voluntary motion, the stools and urine are voided involun-

tarily; respiration is more or less embarrassed, but not stertorous; the pulse is strong, frequent, and full; the temporal and carotid arteries beat strongly; and the skin is generally warm and natural. Cerebral congestion is almost always general throughout the brain, but it is also, although rarely, local, affecting only one hemisphere; and, owing to the numbness and temporary paralysis thereby occasioned being confined either to one limb or to one side of the body, simulates apoplexy, or paralysis from hæmorrhage in the brain. That these local symptoms are, however, owing to partial congestion, and not to hæmorrhage, is evinced by the celerity with which they disappear under judicious treatment. When the cerebral congestion is very great, it constitutes a form of *apoplexy*, noticed in the article on that disease, and may occasion death without any further lesion than congestion merely.

142. ii. *Appearances on dissection.*—The scalp, and even the bones of the cranium, in some cases, are of a red violet colour, and allow of a considerable quantity of blood to escape upon being divided. The vessels, and particularly the sinuses, are filled with dark blood. When the arachnoid of the pia mater is separated from the brain, a reddish patch, more or less deep, is formed, the vessels running through it being gorged with blood. The surface of the convolutions are of a more or less dark colour; and, when the cortical substance of the brain is divided, it is of a deeper hue than natural, the orifices of the cut vessels giving out drops of blood proportionate to their size. Upon dividing the medullary structure, which is usually not so white as in health, myriads of minute specks, becoming small bloody drops, rapidly form on the surface. The large vessels, and particularly the veins of the brain, are gorged with blood. When a person cured of repeated attacks of cerebral congestion, dies of a different disease, morbid appearances are seldom detected in the brain.

143. iii. *Terminations and Complications.*—Cerebral congestion may occasion *meningitis*; or *inflammation* and *softening* of the substance of the brain; or *hæmorrhage* in some situation within the cranium, giving rise to complete *apoplexy*, or *palsy*, or both; and serous effusion in the ventricles, or between the membranes; many of the cases of *apoplexy*, attended with extravasation of blood, thus commencing in congestion, the extravasation being a consecutive change. It may also supervene on organic changes of the heart and lungs, and in the progress of various fevers, and thus be complicated with these diseases.

144. iv. *Causes.*—The causes of this state of the cerebral circulation, are those which have been already detailed in the articles *APOPLEXY* and *Cerebral Plethora* (§ 134.).

145. v. *Treatment.*—*Blood-letting*, general, local, or both, to an extent which the constitution, habit, and symptoms of the patient indicate, are requisite. Next to blood-letting, active purging by calomel, followed by a dose of senna, croton oil, or some other active cathartic, and promoted by strong cathartic injections, such as the oleum terebinthinæ, oleum ricini, extr. colocynth. comp., &c. are required, and should be repeated, so as to procure copious evacuations, and keep up sufficient action in the alimentary canal. The effusion of cold water on, or cold sponging the head, is gene-

rally beneficial; and when the temperature is increased, and the countenance and conjunctiva flushed, a thick oilskin should be placed under the patient's head, which ought always to be kept elevated, and covered with cold epithemis. Due attention should be constantly paid to the state of the evacuations. Accumulations of bile in the gall bladder or hepatic ducts, and of fecal matter and morbid secretions in the alimentary canal, frequently predispose to or induce an attack, which will seldom altogether yield to the means employed, unless these morbid collections are removed by appropriate means; and as long as the evacuations continue unhealthy, we may infer that the chief cause of disorder is not altogether removed. (See *Treatment of Apoplexy*.)

BRAIN — INFLAMMATION OF THE. — CLASSIF.

1. *Class*, Febrile Diseases; 2. *Order*, Inflammations (*Cullen*). 3. *Class*, Diseases of Sanguineous Function; 2. *Order*, Inflammation, (*Good*). III. CLASS, I. ORDER (*Author*, see *Preface*).

146. NOSOL. DEFIN. — *Pain of the head more or less violent, with suffusion or prominence of the eyes; generally tumid or flushed countenance, delirium, or sopor, or both, or a marked predominance of either with symptomatic fever; and frequently with lesion of the senses and functions of relation.*

PATHOL. DEFIN. — *Inflammation of either the membranes or the substance of the brain, or of both, generally with predominating lesion of either the one or the other.*

147. The recent researches of anatomists and pathologists have tended to advance our knowledge of the phenomena of inflammations of this important organ. The investigations of M. MAGENDIE, who has shown that its membranes exhale in health a limpid serum for the purposes of protecting the parts they surround, of facilitating the movements to which they may be subjected, and of accommodating and imparting a certain degree of superficial pressure, so that they may not suffer from the varying positions and states of vascular plethora to which they are obnoxious, have indirectly thrown considerable light on the pathology of the brain. Much, however, is still required to be known, not only as to the further relations which these membranes hold to the cerebral organs, in the performance of their healthy functions, but more particularly as respects the connection which subsists between their organic lesions and their symptomatic or functional disorders.

148. We know that the more internal and the most vascular of these membranes are chiefly appropriated to the distribution of the circulating fluid by means of the minute capillaries which it transmits to the external surface of the brain. We may thence infer that the functions, and even the organic conditions of the brain, in these situations especially, will be greatly modified, or even altogether changed, by the varying condition of the circulation in this membrane. When, therefore, it is the seat of inflammation, disease will be more or less extended to the substance of the brain; and will more or less influence the functions of this organ, particularly in the parts which it supplies with blood. The membranes, however, exterior to the pia mater, may be affected to a considerable extent without this

latter participating much in the disorder: and here our knowledge is both imperfect and deficient in precision: for we are not enabled to state that in such cases the functions of the brain itself are undisturbed, or, if disturbed, in what manner the lesion of these exterior membranes affects this organ; and, being imperfectly informed respecting all the offices of these membranes, we are less able to trace the relation between healthy function and the phenomena which inflammation of them present. Surrounded thus with difficulties, which the advance of science will doubtless diminish, are we therefore to leave the subject without investigation, or relinquish the attempt to place in order and explain those facts which we have already obtained, and which may be made subservient to a further elucidation of the subject?

149. In no other organ of the body is it so difficult as in the brain, to trace the relation between demonstrable change of structure and morbid manifestations of function. This is partly owing, no doubt, to the circumstance of its being a double or symmetrical organ; lesions seated only in one half or side of the brain, when unattended by absolute disorganisation, not occasioning a corresponding degree of disorder as long as the same part of the other side is unaffected. *Delirium* has been conceived to be a symptom indicating the existence of inflammation of the membranes of the brain; yet *delirium* is a disorder of those functions which we conceive to be performed by the cerebral substance itself; and every experienced practitioner must have observed, and numerous are the cases on record, in which inflammation to a great extent, and all its consequences—as thickening, adhesions, effusions of lymph, or even of purulent matter—have been observed, and yet there had been no *delirium*. It is therefore to be inferred, that, when *meningitis* is accompanied with *delirium*, the disease extends more or less to the pia mater or parts enclosed by it. This inference, however, might lead to a conclusion which seems not well founded, viz. that it is impossible to distinguish *meningitis* as a disease independent of inflammation of the substance of the brain. This, doubtless, is often difficult, because both diseases frequently co-exist in different degrees, or co-ordinately; yet still an extensive experience will show that they often exist separately: and hence the necessity of ascertaining what are the characters which are proper to each. In respect of diagnosis, the subject possesses interest; and although the treatment in both is, in its principal points, the same, yet on some occasions it requires to be modified.

BRAIN — INFLAMMATION OF ITS MEMBRANES.

SYN. *Meningitis, Paraphrenitis et Phrenitis*, Auct. Var. Recent. *Arachnitis*, Parent and Martinet. *Cephalitis Meningica*, Good. *Phrénésie*, Pinel. *A. éningite*, Fr. *Die Hirnhautentzündung*, Ger. *Brain Fever*.

150. DEFIN. *Acute pain in the head, with intolerance of light and sound; watchfulness, delirium; flushed countenance, and redness of the conjunctiva, or a heavy suffused state of the eyes; quick pulse; frequently spasmodic twitchings or convulsions, passing into somnolency, coma, and complete relaxation of the limbs.*

151. We are rarely enabled to distinguish between inflammation of the arachnoid membrane and that of the pia mater by the symptoms during life, I shall therefore comprise under the head of *meningitis* inflammations affecting one or more of the membranes of the brain.

152. SYMPTOMS. — As the uses of the cerebral membranes are not rendered sensible by manifest functions, it may be concluded that diseases of these parts may exist to a considerable extent, without any distinctive symptoms. The justness of this observation is but too frequently confirmed by experience; for there are few practitioners who have diligently employed their opportunities of *post mortem* research, and have not observed appearances of inflammation, without much disorder of the intellectual faculties, or of the movements of the body, having been manifested, almost up to the moment of death. Such instances are not rare, particularly in persons advanced in life. More frequently, however, when the membranes are inflamed, the adjoining portions of the brain, the functions of which they are probably intended to facilitate, evince some sort of disorder, particularly of their usual functions. These symptoms, although indirect, are generally similar to those of the inflammation of the cerebral substance itself, and are the chief guides to lead us to the recognition of meningitis.

153. The symptoms vary according to the seat of the inflammation, the stage at which it has arrived, the severity of the attack, and the celerity of its progress. The disease in its usual form presents three periods: 1st, that of invasion; 2d, that of fully developed inflammation; and, 3d, that of compression. Some one of these periods, however, does not always exist, particularly when the inflammation is very general or very circumscribed, or when it is very acute or very chronic in its progress. Meningitis affects more frequently that part of the membranes which covers the convexity of the cerebral lobes, in adult subjects; and the portions about the base of the brain, in young children.

154. *Acute meningitis* of the convexity of the cerebral lobes is attended with violent pain, which is exasperated at intervals, and often with stupor or somnolency. It occupies various regions of the cranium, the frontal, occipital, syncipital, &c., and is augmented by motion, particularly by rotation of the head, which, in children, is often drawn backwards. In this class of patients the pain is expressed, particularly upon being roused, by a *peculiar cry*, which the experienced observer recognises as a diagnostic sign of the disease, and after uttering which the infant sinks into a somnolent stupor, in which it grinds its teeth frequently. The functional derangements occasioned by meningitis are usually of a *general* character, although the inflammation is more frequently of limited extent. This is owing to both sides being attacked at the same time; cases where the meninges are inflamed on one side only being very rare.

155. *a.* Pain in the head is generally preceded by chills or rigors, which may be viewed as the result and indication of the formation of the disease; but cases not infrequently occur, wherein the foregoing signs in a greater or less degree precede the rigors even for a considerable time. The face at first is often pale; but, as the

disease becomes fully developed it is more frequently slightly tumid, flushed, and expressive of pain, and the eyebrows knit or contracted; the eyes are heavy or brilliant, injected and watery, generally nearly shut, incapable of bearing the light, and the pupils contracted. The patient thinks he sees fire, or scintillations of light; and sometimes the colours of bodies appear differently shaded. The slightest noise is insupportable, and all the senses are in a state of morbid activity. His answers are brief and quick, and there is an evident activity of mind, but as yet no delirium. His disposition, however, seems changed; and he becomes impatient, irritable, abrupt, and quick in his manner, and his countenance is expressive of irritation and pain. The temperature of the head is now greatly increased; the pulse is frequent and developed; the tongue rather dry, its papillæ more or less erect and distinct; thirst is complained of; the urine is scanty and high-coloured, and the bowels are obstinately constipated, but in some instances, in children, either relaxed or irregular, and the evacuations morbid and offensive. From the commencement of the attack there is generally vomiting, particularly in children, which recurs at intervals, is unattended with tenderness or pain at the epigastrium, and is manifestly sympathetic of disease within the head. In adult subjects, vomiting is sometimes absent. It is not infrequently remarked, that this stage either does not occur or passes unobserved in aged persons. The patient loses suddenly his recollection, as in congestion only of the brain; but to this succeed febrile symptoms, distinguishing it from this latter affection.

156. *b.* After an indeterminate period, commonly varying from one to three or four days, according to the intensity of the attack, violent delirium comes on, but not constantly. If the pain in the head continues, it is not complained of by the delirious patient; and the senses are no longer intolerant of their natural excitants; the pupils commence to dilate or to contract, and strabismus supervenes; the countenance has a convulsed appearance; the lips are drawn somewhat to one or both sides; the pulse is more or less developed, sometimes irregular and trembling, and is rarely at this period feebler or slower than natural; and the tongue presents the same appearances already noted; the thirst, and frequently the vomiting, still continue. The temperature of the head continues excessive, but occasionally fluctuates, whilst that of the rest of the body is often not materially augmented.

157. *c.* To this state succeeds more or less marked exhaustion, which should not be taken for commencing resolution of the disease. The patient ceases to scream; and the symptoms of violence subside; but to these succeed startings of the tendons, carphologia, convulsive motions, and sometimes cramps, chiefly in the upper extremities. The pupils are dilated, contract with difficulty on exposure to light; the eyes are rolled in their orbits, become insensible, as well as the other senses, to the ordinary excitants; and a complete calm takes the place of the violent delirium; the patient even not answering questions put to him. He has had no sound sleep excepting a fatiguing stupor; he is now plunged in a profound coma. The limbs are, up to this

time, rigid and contracted, but soon become completely relaxed. This state is owing, generally, to the effusion of serum, which has now taken place; but it sometimes may exist without increased effusion; injection and congestion of the vessels of the brain, or compression, from whatever other cause, also producing it. At this period of the disease the face is pale, the eyes inexpressive, dim, half open, and drawn upwards; the cheek bones prominent, the temples hollow, the nose pinched, the ears cold; the lips dry, applied closely to the teeth, which are covered with a fuliginous coating at their base; the tongue is dry, hard, and brown; deglutition difficult, the abdomen distended with flatus, and the fæces and urine voided involuntarily. The skin is either cold, or covered by a viscid sweat; the pulse is small, unequal, or irregular; the respiration slow, sometimes stertorous; the expired air is cold and foetid; and the patient dies generally in the course of a very few days, or from two to three weeks, and but rarely later.

158. These are the principal symptoms of acute meningitis of the cerebral hemispheres. They present irregular periods of exacerbation; the heat of skin and character of countenance varying at different times without any evident cause. The stages of the disease are not precisely marked; either of them may be wanting, and sometimes they seem as if confounded with each other. When the disease terminates favourably, the symptoms sub-side gradually; resolution taking place, sometimes with, but as frequently without, critical phenomena.

159. According to the observations of MM. PARENT, MARTINET, and ROSTAN, when the membranes of the base of the brain, or of the ventricles, are the seat of the inflammation, the symptoms are somewhat different. The patient then experiences less delirium, or even preserves his intelligence almost entire; his faculty of attention, and some of the other intellectual powers, being only diminished. He answers slowly, but rationally, to questions put to him; somnolency is almost continued, and coma more quickly supervenes. In other respects the symptoms are the same. Cephalalgia is complained of chiefly at the bottom and above the orbits; in general, the symptoms of irritation and excitement are less strongly pronounced than in the preceding form of the disease.

160. *B. Chronic meningitis* differs from the acute chiefly in the less intensity of the symptoms, and slow progress of the disease. In many cases the functions of sense and locomotion are but slightly disturbed, and usually the intelligence is unimpaired; at least, as long as the inflammation does not affect the membranes of the convexity of the hemispheres. When seated, however, in this place, according to M. BAYLE, who has devoted considerable research to this subject, delirium frequently is also present, but it is seldom violent; sometimes it is taciturn; and the patient generally is engaged with lofty or ambitious ideas.

161. Chronic meningitis commonly succeeds to the acute form of the disease; but it often presents the chronic characters from the commencement. There is generally continued head-ach, with slight somnolency, sluggishness, incapacity and want of desire for intellectual

exertion, moroseness, irritability of temper, sometimes confusion of ideas, embarrassment of speech, and delirium, terminating in confirmed mania or maniacal idiocy. The motions of the limbs are slow, difficult, or painful; and their muscles are subject to involuntary motions and twitchings, and sometimes are not under the control of volition, or are altogether paralytic. Vomiting and convulsions are rarely present, excepting in *infants*, where they are often the chief or almost only signs. In *children*, the peculiar knitting of the eyebrows, retraction of the angles of the mouth, whining or peevish cry, stupor, grinding of the teeth, scanty urine, obstinate costiveness, and the increased heat of the head, are the chief symptoms; these being similar in kind, but much milder in degree, than those accompanying the acute or sub-acute states of the disease. In many cases, both in children and adults, the functions of organic life present but few lesions of a marked description until towards the last period of disease, or shortly before death. It will be perceived that many of the phenomena here stated, belong to disease of the brain,—a circumstance which must necessarily obtain, for as the membranes surround the whole of this organ, and are one of the chief media of distributing the blood-vessels to it, any disease affecting its structure, or modifying the quantity or properties of the fluid secretion furnished by these membranes, for its protection, &c., must necessarily implicate the state of its functions.

162. *C. The duration* of meningitis necessarily varies with its intensity. In its *acute* form it extends from three or four days to twenty-eight, and even thirty; but more frequently from seven to fourteen days. In many cases it is difficult to assign the period of invasion; pain and somnolency having been complained of even for days before the occurrence of chills or rigors. The disease also not infrequently supervenes on other affections, and occasionally becomes complicated with them, particularly in the course of *whooping-cough*, and diseases of the prima via, when its invasion may be overlooked, or with difficulty ascertained. The more *chronic states* of meningitis have no determinate duration: they may proceed gradually and in a slight form, when, unexpectedly, from some exciting cause, or even without any evidence of such occurrence, they may assume an acute character, and terminate more or less rapidly.

163. *D. The organic changes* consequent upon inflammation of the cerebral membranes are observed chiefly in the pia mater, the arachnoid, and the reflection of the arachnoid covering the dura mater, and not infrequently, also, in the cineritious substance of the brain. These consist principally of injection and impregnation of the pia mater with blood, &c.; loss of the transparency of the arachnoid; effusion of serous or sero-albuminous fluids; and the various lesions particularly described in the preceding sections (§ 22—28.).

BRAIN—INFLAMMATION OF ITS SUBSTANCE.—
 SYN. *Phrenesis, Phrenismus, Auct. Var. Encephalitis, Enkephalitis.* Hildenbrand. *Cephalitis, Auct. Var. Recent. Encéphalite, Bouillaud* and other French Pathologists. *Cérébrite, Foville. Cephalitis Profunda, Good. Gehirnenzündung, Ger.*

164. DEFIN. *Pain of the head; vertigo; altered sensibility; spasms or contractions, of one or more limbs; excited or deranged functions of sense and intellectual power; rapidly terminating in coma.*

165. I have stated that meningitis manifests itself to our senses chiefly by the lesion of the cerebral functions; and that this is occasioned in two ways, viz., by deranging and impeding the functions of the brain, which these membranes are intended to facilitate; and by imparting the inflammatory action to those parts of the brain contiguous to them. But although the relative connection of parts thus necessarily increases the difficulty of distinguishing the symptoms proper to the membranes, or to the brain itself, still there are certain signs which enable us to infer the degree to which either may be separately affected. We shall see in the sequel, that, in cerebritis, the organs of voluntary motion exhibit frequently morbid phenomena which are generally limited in extent; whilst we have seen, in meningitis, these organs are affected generally, and seldom or ever partially, excepting when complicated with inflammation of some portion of the brain; and if, in cerebritis, all the voluntary actions are affected, the inflammation has commenced in the membranes, and extended itself to the substance of the brain,—the disease existing as meningitis and cerebritis conjoined, which is, perhaps, its most common state, and in which I shall presently consider it.

166. SYMPTOMS.—*A. The more immediate functional derangements.* The functions of the brain consisting of sensation, volition, instinctive desires, intelligence, and moral sentiments, it is evident that the phenomena of the disease should be sought after in this series of manifestations; and that they will vary, in respect of their particular states, their intensity, and progress, according to the seat, the nature, and extent of the organic change.

167. *a.* When *cerebritis is general*, it often presents the same functional disturbances, and the same progress and stages, as meningitis: it is, indeed, very probable that both diseases co-exist, and that the inflammation commences in the pia mater. However, when the whole cerebral mass is inflamed, coma, with relaxation of all the limbs, takes place much earlier than in meningitis; and the disease develops itself with extreme rapidity; the symptoms of vascular excitement scarcely showing themselves, or, at least, for a very short time; and being frequently altogether absent. This difference is readily explained, when we consider that, in meningitis, the brain being only secondarily and slightly affected, it may still exercise its functions, although in a deranged manner; whilst in general cerebritis, the change being extensive, its functions must necessarily be suspended. The patient, after a rigor, which ushers in this as well as the majority of other inflammations, sometimes loses recollection; but he has generally experienced other symptoms previously, such as obstinate pain of the head, twitchings, pricking sensations, slight numbness or diminution of the sensibility, with painful muscular action, vertigo, sudden want of recollection, and tinnitus aurium. Sometimes the sensibility is morbidly increased at this stage, as well as the functions of sense; the intellects are active, or excited; and there is watchfulness, with other

analogous symptoms, for a longer or shorter period before the patient is seized with rigors and insensibility.

168. *b.* These *precursory symptoms* M. ROSTAN considers as the result of an incipient disorder, which he conceives to be local congestion, and that inflammation has not then taken place; but they are, more obviously, signs of an early period of inflammatory action. These symptoms are frequently accompanied with general signs of plethora or determination of blood to the head; the pulse, particularly of the carotids, is hard, or full and developed; the countenance is injected; the skin hot, &c. The same precursory signs are likewise observed in softening of the brain; but in this affection the pulse is not augmented in frequency or fullness, the skin is cold and pale, and the countenance pale or shrunk. The symptoms now described indicate, at least, that morbid action has commenced in the brain, and that it is not so extensive or intense as not to subside under judicious treatment. But when the patient has had rigors, the functional disturbance, especially of locomotion, is particularly marked: then ensue clonic or tonic spasms of the muscles, such as startings of the tendons, carphologia, convulsions, cramps, rigid contraction of the limbs, &c. At a more advanced period, particularly when effusion supervenes, paralysis or relaxation, and loss of sensibility of a limb or limbs, takes place.

169. *c.* When cerebritis is *general* (which is never the case without the pia mater being inflamed), these symptoms affect all the limbs simultaneously; when *local*, only some of them, according to the seat of inflammation. Spasms, convulsions, or paralysis, affect also the muscles of the face; there is a falling down of the upper eyelid; the eyelids are shut and contracted; the commissures of the lips are drawn to one side, either by their natural tonicity, when the antagonist muscles are paralysed, or from a morbidly increased action. Sometimes this exists on both sides, producing retraction of the angles of the mouth. Very frequently the muscles and limbs are remarkably painful; so that, when attempts are made to move them, or to straighten those that are contracted, or upon attempting to move himself, the patient screams out.

170. *d.* In *partial cerebritis*, the action of the muscles and the sensibility of the surface are also partially, but not permanently, affected; some parts being less disordered, whilst the affection extends to others; or they all become more severely and permanently diseased; the spastic contractions, which existed at first owing to inflammatory irritation, giving place to paralysis, in consequence of pressure or disorganisation. The intellectual faculties are also frequently disturbed. The patient's answers are abrupt, rapid, sometimes incoherent, and at other times made very slowly. When merely one hemisphere is affected, it has been supposed that the functions of the other will proceed so as to prevent the appearance of much disturbance of the mental faculties; but this may or may not be the case; and, at least, can only occasionally obtain. The mental disturbance, which is extremely various in its forms and states, according to the part of the brain affected, exists only during the first days of the disease, and is soon displaced by coma.

171. *e.* At the commencement, particularly when cerebritis is general, or affects the periphery or more superficial parts of the brain, as in meningitis, or meningitis complicated with superficial cerebritis, the functions of the senses are morbidly increased, the least light or noise, or the slightest touch, being insupportable; but when the disease is seated in the centre of the brain, where the senses transmit their impressions, there is either perversion, or complete loss, of these functions. The pupils are then frequently dilated and insensible; the eyes unaffected by light, the ear by sounds; and the other senses are similarly disturbed; the patient is either watchful, or is oppressed by a somnolency intermediate between sleeping and waking; and numbness, with twitchings, or local convulsions, are generally observed.

172. In the course of a period varying from one to three or four days, or sometimes earlier, and occasionally later, the symptoms are changed, owing to the local affection having advanced to disorganisation. At this period, copious effusion of serum often takes place, occasioning symptoms of compression. The spasms and convulsions are replaced by relaxation and immobility; and the senses are paralysed, not only on the side opposite to the cerebral lesion, but on both sides simultaneously, owing to the healthy parts of the brain being compressed by the effused serum, or by the tumefaction of the parts inflamed. Sensibility diminishes rapidly, and is at last abolished; the intellects are obscured, and at last overwhelmed, and the patient becomes profoundly comatose, or, in the less acute or chronic cases, hemiplegic, and sometimes ultimately apoplectic, or epileptic.

173. *B. The mediate symptoms.* — During the first days of the disease, the countenance is full and coloured; the eyes brilliant and animated, their expression unusual; the temporal arteries, as well as the carotids, beat strongly; there is no appetite; the tongue is white, loaded, red at its margins and point, and the papillæ developed; there are nausea and vomiting; the bowels are co-tive; but occasionally in children there is a diarrhœa from the commencement, and the evacuations are morbid and offensive; the skin is warm, the pulse strong and frequent, and the respiration accelerated. At a later period, a very manifest change ensues; the countenance is expressive of pain, irritation, and chagrin; the features begin to sink and become pale; the eyes dull and half closed; and thirst is no longer complained of; deglutition is difficult, or cannot be accomplished; vomiting is produced with difficulty; the abdomen is distended with flatus; and the fæces are passed involuntarily, as well as the urine, which sometimes accumulates in the bladder from paralysis of this organ; the skin becomes cold, or covered by clammy sweat; the pulse is unequal, irregular, or variable; the respiration laboured, or stertorous; and the patient sinks. In rare cases, at this stage of the disease, the symptoms diminish, and the functions gradually assume their natural states, either with or without the occurrence of phenomena which may be regarded critical. The alterations of structure produced by cerebritis are fully described in preceding sections of this article (§ 48. *et seq.*).

BRAIN — INFLAMMATION OF THE MEMBRANES AND SUBSTANCE OF THE. — SYN. *Phrenitis* (from φρήν, the mind); *Encephalitis*,

Cephalitis (from κεφαλή, the head), FRANK and HILDENBRAND. *Phréusie*, *Encéphalite*, Fr. *Hirnentzündung*, Ger.

174. DEFIN. *Violent pain in the head; prominent suffused eyes; flushed countenance; violent delirium, followed by profound sopor.*

175. Having described inflammation affecting chiefly either the membranes, or the substance of the brain, I now proceed to consider inflammation attacking these structures simultaneously, or rapidly extending from the one to the other, chiefly from the former to the latter. This is certainly the more common form in which inflammation seated within the cranium manifests itself in adults, particularly in hot countries, and in temperate climates during hot seasons. In children, however, a more or less evident limitation of the inflammatory action to either the membranes, or the cerebral substance, especially the former, is frequently perceived; and the same remark may be extended to aged persons, in whom the substance of the brain is more liable to be affected, chiefly in a sub-acute or chronic form. That the division which I have made of inflammations of the brain, is founded in truth, and that their diagnosis may be established in practice by a judicious and experienced physician, I have had numerous opportunities of proving at the Infirmary for Children, where the cases admitted with inflammations seated within the head have been entered as cases of meningitis, cerebritis, or encephalitis, as the membranes, the substance of the brain, or both, respectively, were considered chiefly affected.

176. It may be supposed, that the distinctions argued for, granting their accuracy, tend to little practical advantage. This is, however, a very serious mistake; and I cannot more fully demonstrate it, than by the following fact: — About ten years since, I was requested to see a child, attended by an able and scientific practitioner, who considered the case as meningitis, which had terminated in effusion; or, in other words, of acute hydrocephalus in its advanced stage, and perfectly beyond the reach of art. After an attentive consideration of its history and existing state, I expressed the opinion, that the disease was inflammation, chiefly affecting the substance of the brain, and that a decided treatment founded on these views might still be successful. Leeches applied behind the ears, and around the occiput, with the means which will be hereafter detailed, succeeded in restoring the child to health in a few days. Since this instance, I have witnessed similar mistakes. The diagnosis, prognosis, and the treatment adopted in these cases proceeded on the important fact already stated (§ 167.), that cerebritis will, owing to the turgescence of the inflamed organ, give rise at a very early stage of the disease to the most profound coma, relaxation of the limbs, and many of the symptoms occasioned by effusion of serum; whilst the greater temperature of the head, and strength of the pulsation of the carotids in the former, will often, independently of other signs connected with the history of the case, evince its real nature.

177. SEAT. — In the greater number of cases, inflammation commences in the pia mater, and extends itself to the arachnoid on one side, and to the cortical substance of the brain on the other;

and not infrequently also to the arachnoid covering the dura mater, and the deep seated structures of the brain. It is also very probable that more than one of these different structures may be nearly simultaneously affected. It may, however, originate differently when it arises from external injury; as in the dura mater, the substance of the brain itself, or the arachnoid.

178. I. SYMPTOMS. — *A. Premonitory.* Encephalitis generally commences with a sense of heat and fulness in the head; frightful dreams, and unquiet sleep; forgetfulness; confusion of ideas; dimness of sight; vertigo; turgidity of the face and eyes, and moroseness of temper. These symptoms generally precede the occurrence of chills or rigors, and are entirely absent when the disease proceeds from external injuries. In *children*, unusual somnolency, or wakefulness; startings in sleep, or fretfulness; aversion from sudden or quick motion; dryness of the mouth and nostrils, and not infrequently a voracious appetite, are the chief precursory symptoms.

179. *B. The invasion, or first stage* of encephalitis, is indicated by severe chills or rigors, to which succeed a burning heat of the head; urgent thirst; sometimes, even thus early, an unnatural absence of thirst, and violent delirium; jactitation of the body; intolerance of light; fixed, pulsating, heavy, compressing, and most severe pain of the head, alternating frequently with stupor. Febrile heat rapidly increases, and the head becomes more turgid and hotter; the eyes more prominent, suffused, watery, and intolerant of light; the pupils are contracted; the eyelids are generally shut, or imperfectly open; the eyebrows are knit, and the countenance is threatening and fierce. Hearing is quicker, is attended with ringing in the ears, and intolerance of sound. Epistaxis sometimes occurs, generally to a small extent, and with only transitory benefit. Insomnia, and *delirium* of various forms—more-e, taciturn, furious, &c.—supervene; and, in proportion as the cerebral organs are excited, those viscera which are supplied with the ganglionic nerves are rendered torpid, the patient being insensible to the wants of the digestive organs.

180. *C. The second, or advanced stage*, is generally characterised by a marked diminution of the sensibility which was in the preceding period morbidly increased. The pulse, which was at first frequent, hard, and full, becomes slower, fuller, and softer, and, in some cases, quicker, smaller, or harder. The skin is dry; the urine scanty and high-coloured; the tongue is dry, and loaded at the root; the bowels constipated. In some cases, particularly those in which the cerebral substance is early and generally inflamed and turgid, instead of phrenetic delirium, an apoplectic sopor, often preceded by convulsions, quickly supervenes; with a slow pulse; stertorous, slow, or laborious breathing; turgid or bloated countenance; startings of the tendons; involuntary evacuations; torpor of the senses, and flaccidity of the limbs. In those cases in which delirium is present, and the pulse quick and hard, a similar state of coma to that now mentioned takes place sooner or later, if not averted by medical aid. In the one, the first stage is short and indistinctly marked; in the other, it is long, and often continuing the greatest part of the whole duration of the disease; the second

stage sometimes appearing suddenly, and terminating rapidly. In both these states of the disease, the difficulty of swallowing is great, so that fluids are sometimes regurgitated by the nose; and when the substance of the brain is chiefly affected, deglutition is often nearly, or altogether abolished in the most intense cases. In this stage, the pupil becomes at first dilated, and occasionally again contracted; the patient, in some cases, squints, or has double vision; his speech is often much affected, and his mouth is drawn to one side. Deafness also comes on, or increases, and the sopor, or coma, is more profound; most probably owing either to incipient effusion of fluid, or to greater turgidity of the capillaries and veins, or to both these combined, in a part or the whole of the encephalon. The comatose symptoms appear early or late, according to the intensity of the disease, the extent to which the cerebral structure is affected, and the tone and energy of the system. They sometimes partially subside, again recur, or alternate with convulsions. As the disease advances to an unfavourable termination, the pulse becomes remarkably quick, irregular, or intermittent.

181. *D. Duration.* — Encephalitis usually reaches its acmé about the third or fourth day. It then continues in full strength for several days, exhibiting slight remissions and exacerbations, and simulating continued fevers. In favourable cases, a *change* is sometimes observed on the fifth, seventh, or some other critical day, unless a fatal termination occur; and is generally attended with either copious perspiration, or hæmorrhage from the nose, free evacuations from the bowels, or a discharge of urine depositing a copious sediment. The disease may assume a *sub-acute* or a *chronic* form, presenting a diversity of symptoms, especially in its chronic state, according to the particular part of the brain affected; or it may proceed in a very slow, slight, and insidious manner, and escape detection until a dangerous or fatal change has taken place. The more chronic states may follow an imperfectly cured acute attack, and the latter may suddenly supervene on the former.

182. II. CAUSES. — *A. Predisposing.* The sanguineous and nervous temperaments; the epochs of infancy, childhood, and youth — particularly to meningitis; the period of dentition; advanced age — especially to cerebritis in a sub-acute or chronic form; the male sex; a large head and short neck; children of scrofulous parents, and those who evince precocious talent or acquirements; persons subject to perspirations or eruptions on the head; early or habitual exertions of the mental powers; the indulgence of the more active passions and affections; encouragement of vindictive feelings; anger; continued watchings; venereal excesses; the use of spirits and narcotics, as opium, tobacco, &c.; a too warm state of the head; suppression of epistaxis, hæmorrhoids, or of any other accustomed secretion or evacuation; the neglect of sanguineous depletion after the habit has been established; the healing up of chronic ulcers and eruptions, and other disorders of the brain, are most frequently the predisposing circumstances and causes of the disease.

183. *B. The exciting causes.* — *A.* Those which act more *directly* on the encephalon, are blows, fractures, falls, counter-strokes or concussions of

the head, all which may not be followed, for many days, by any evident symptoms; whirling children in the air, or tossing them in order to quiet them, or rocking them rudely in cradles; the improper use of narcotics and stimulants in order to quiet them; the action of the sun's rays; protracted study; excessive joy; violent fits of anger; excessive desire; jealousy, and all the exciting passions; unusual exertion or irritation of the senses of sight and hearing; exostoses on the inner table of the skull, and the absorption of purulent or morbid matters into the circulation.

b. The causes which act more remotely or indirectly, are the diseases with which I have stated encephalitis to be sometimes complicated (§ 186.); nervous or bilious headaches; all painful affections; mania; inflammations of the ear; disorders of the stomach, diaphragm, liver, and bowels; affections of the sexual organs; ingurgitation and intoxication; the exanthemata, particularly when imperfectly developed on the external surface, or upon the disappearance of the eruption; the metastasis of gout, rheumatism, and erysipelas; suppressed hæmorrhages and evacuations, particularly the menses and the urinary secretion; the accumulation of sordes and morbid secretions in the prima via and gall bladder; the ingestion of irritating and narcotic poisons; indulging in cold punch (FRANK); violent fits of coughing; long exposure to great cold, and, according to GOELIS, the too free use of *belladonna*, and other narcotics, in the cure of whooping-cough.

184. III. DIAGNOSIS.—*A. Characteristic symptoms.* *a.* Pain is an early sign, but the patient often ceases to complain of it very soon, particularly if the cerebral substance be chiefly inflamed; when it is also gravative, and attended with stupor from the commencement. It is most acute when the membranes are affected, and is always aggravated by shaking the head, and the erect position. When the disease supervenes in the progress of fevers and bronchial affections, pain may not be complained of, owing to the impure state of the blood having blunted the sensibility. *b. Watchfulness and sleep.*—Insomnia is generally present during the first days, when the membranes are affected, and, in children, starting from sleep, and screaming. Heaviness, somnolency, sopor, or even coma, often preceded by convulsions, are early present when the substance of the organ is the chief seat, or the membranes extensively affected, and supervene early, but without convulsions, when the disease occurs in the course of fevers and bronchial affections; but a refreshing sleep is never enjoyed, unless after a favourable change. *c.* The senses, particularly sight, hearing, and touch, are all morbidly active in the first stage, especially when the meninges are inflamed; but they are nearly abolished at this period, when the cerebral substance is chiefly affected. The eye often indicates mental oppression, even when bright and staring. The sensibility of the surface is unnaturally increased in meningitis or superficial cerebritis, but is diminished when the substance of the brain is deeply affected, and in the advanced stage, when the membranes generally are inflamed. In partial cerebritis, the sensibility of a limb, or part only, is often lost, and it may be conjoined with spastic rigidity, or paralysis of the same or of another part. *d.* The intellectual and moral faculties are more

or less disordered; they are unusually excited, or violently deranged, early in the disease; but sopor frequently supervenes without being preceded by this state, when the cerebral structure is inflamed. Reverie or wandering of the mind during night, is the least important form of mental disturbance, indicating a slight affection of the pia mater, extending to the cineritious substance; delirium through the day, and watchfulness in the night, are the most dangerous, and attend a severe affection of the membranes. *e.* The respiration is often quicker in proportion to the pulse in the first stage, and slower in the second; and in the torpid or somnolent state, when the substance of the organ seems chiefly to be affected, is often attended by deep-drawn sighs. *f.* The digestive organs are much affected, particularly in children. There are nausea and vomiting, especially at the commencement, and torpor of the bowels. As the disease advances, however, the bowels often become free, or even relaxed. *g.* The muscles and limbs are more or less pained, contracted, convulsed, particularly in the first stage, and when the cerebral structure is inflamed. The convulsions are often general or severe, on the supervision of the disease, in young subjects. They may be soon followed by coma, which may pass off, and the convulsions again recur, and terminate life. When the cerebral substance is partially affected, the spasms and contractions may be confined to one or more limbs, whilst the rest are relaxed, or complete paralysis may ensue. In the last stage muscular power is generally lost, and the limbs are flaccid. *h.* The pulse is extremely variable. At first it is not remarkably frequent; but it often becomes slower, and again quicker than ever, and at the same time weak, small, irregular, or intermittent. It may be at one time either slow or frequent, and in a few minutes the reverse; but it is never natural in respect of fulness, regularity, or strength. It is generally stronger and fuller in the carotids than elsewhere, and in this situation it ought always to be felt.

185. *B. Encephalitis* may be mistaken for other diseases; but if attention be paid to the history of the case, and the descriptions now given, this can scarcely happen. It may, however, be confounded with fevers, apoplexy, delirium tremens, mania, and nervous headaches.—*a.* In fevers, the disturbance of the cerebral functions, when prominently marked, generally occurs in their progress, as a complication or consecutive affection. The pulse is always more uniformly frequent and regular than in encephalitis; spasms, convulsions, or paralysis, seldom occur, unless the brain becomes inflamed; respiration is not laborious, nor deglutition difficult; nor are the eyes, countenance, and speech, affected, as in encephalitis. In idiopathic fever, the muscular power is depressed from the commencement, but is neither generally nor partially affected by spasms, contractions, or paralysis, and the stomach is less remarkably disordered. There is not observed that falling of the pulse from its former frequency, afterwards followed by great rapidity, trembling, or irregularity, which take place in encephalitis. In fever, the general febrile symptoms are the earliest and most apparent disease; in encephalitis the functions of the brain, of sense, and of the organs of volition, are prominently and early disordered, and the febrile symptoms much less re-

markable in proportion to the severity of the cerebral disease. When the coma is profound in encephalitis, the heat of the whole body, excepting the head, is either not augmented or depressed. The delirium in fevers also occurs at a remoter period, and is much less violent in its character, than in encephalitis. — *b.* The disturbance of the organic, and particularly the digestive functions, the presence of fever, and the acute character of the disease, distinguish it from *maniacal insanity*. — *c.* The same symptoms, with the frequent addition of delirium, of disturbance of the senses and general sensibility, spasms or convulsions, somnolency, sopor, and paralysis, preclude the possibility of confounding it with *bilious* or *nervous* headaches. — *d.* Somnolency, sopor, convulsions, and slowness of the pulse, distinguish it from *delirium tremens*, in which the spectral illusions, the remarkable tremors, timidity; copious, clammy, fetid perspirations; and the specific cause of the affection; sufficiently characterise the latter, when occurring in a distinct and uncomplicated form. — *e.* The spasmodic or convulsive symptoms, antecedent delirium, the mode of attack, and progress of disease; the absence of paralysis, or its slower accession when the brain is inflamed, distinguish encephalitis from *apoplexy*, in which the invasion is sudden, or more rapid, and the paralysis a simultaneous or consecutive symptom. The relation, however, between apoplexy and encephalitis is often intimate, particularly in cases of partial inflammation, or inflammatory softening, of the substance of the organ.

186. IV. STATES, FORMS, AND COMPLICATIONS. — Besides the more or less perfect limitation of inflammation to either the membranes or the substance of the encephalon, other states may present themselves deserving of remark. — *a.* Encephalitis may result from the *metastasis* of gout, rheumatism, and erysipelas, or it may arise from the *extension* of the last named disease to the brain. In these cases the membranes are chiefly affected; stupor and coma come on early, and are attended with general flaccidity of the limbs, subulcus tendinum, involuntary evacuations, and slowness of pulse; but local cramps, convulsions, or paralysis, are seldom present. — *b.* The disease may be also *consecutive* of other diseases, as of inflammation of the ears (§ 58.), of the bones of the head or pericranium. In these cases it is first extended to the membranes, and afterwards to the substance of the organ; occasioning contraction, spasms, or paralysis of one or more limbs, or muscles of the face, terminating in coma, or alternating with stupor and general convulsions. It may also be consecutive of severe ophthalmia, of inflammation of the parotids or testes, of the kidneys, of inflammation of the mucous surface of the bowels, especially in infants, and of the diseases of the lungs. — *c.* Encephalitis may likewise *supervene on*, and be *complicated* with, the advanced stages of continued and remittent fevers, bronchial and pulmonary affections, hooping cough, exanthematous fevers, particularly scarlet fever and small pox. In all these cases the membranes and superficial parts of the brain are principally affected, generally in a more or less diffused manner, occasioning first delirium, general convulsions of young children, great pain in the limbs, sensibility and soreness of the surface, followed more or less rapidly by sopor, coma,

more rarely by local spasms and paralysis, involuntary evacuations, rapid irregular pulse, &c. The complication with typhoid, continued, and exanthematous fevers, especially those of certain epidemic constitutions, is extremely frequent and important; and has given occasion for the opinions entertained by WILLIS, CHIRAC, WERTHOFF, REIL, PLOUQUET, CLUTTERBUCK, and MARCUS, respecting the proximate cause of fevers. To this complication also TORTI attributes the malignancy occasionally assumed by the remittents and intermittents of the south of Europe. When it thus supervenes on fevers and bronchial diseases, the symptoms are often more insidious, and of a less violent character, although the disease is equally rapid and disorganising. This is probably owing to the depressed state of the vital manifestations, particularly of the organic nerves and vascular system. Owing also to this circumstance, encephalitis, when thus complicated, requires a modified and less depletory treatment. Inflammation of the brain is also not infrequent after apoplectic seizures, particularly in the part of the organ surrounding extravasated blood. In these cases the disease generally occurs from five or six to ten or twelve days after the attack, and is attended with many of the symptoms of partial encephalitis, particularly spasms, paralysis, delirium, &c.

187. V. TERMINATIONS AND PROGNOSIS. — *a.* This is always a dangerous disease, and therefore a very cautious *prognosis* ought to be given. The termination of encephalitis in *health* occurs most frequently in persons of a sound constitution, and who have no hereditary disposition to the diseases affecting the encephalon. This change often occurs on critical days, when it is generally attended by some favourable occurrence, as a copious discharge from the bowels; a genial and universal perspiration; a copious discharge of urine, depositing a sediment; hæmorrhage from the nose, or the presence of the menses; a more natural state of the pulse and respiration; a quiet undisturbed sleep, distinct from the oppressive somnolency or sopor which is one of the chief signs of the severity of the disease; a more moist, natural, and clean state of the tongue and gums; a decline of the temperature of the head, and of all the other symptoms.

188. *b.* A *fatal termination* may take place, 1st, In the inflammatory stage owing to the very general extension of the disease to the membranes and substance of the organ; the pressure and interrupted circulation arising from the turgescence of the inflamed organ annihilating its functions (§§ 48. 167.): 2d, In a further advanced stage, from an effusion of serum, sero-albuminous fluid, or the deposition of false membranes (§§ 21—28.): 3d, In the less acute cases, and at a still more advanced period, from suppuration or inflammatory softening of a portion of the brain (§§ 50—76.): and, 4th, This issue may proceed from any two, or the whole, of these changes being conjoined in the same case. The *indications* of an unfavourable termination are the persistence of the urgent symptoms after treatment; violent delirium, watchfulness, and restlessness; profound lethargy or coma, or the alternation of these states; violent general convulsions, followed by coma, or alternating with it; a morose delirium; retraction of the head; severe pains of the limbs, followed by cramps,

contractions, or palsy; hæmorrhage from the ears; difficulty or impossibility of deglutition; strabismus, or double vision; loss of speech; slowness of pulse, followed by a sudden increase of frequency; a trembling or irregularity of pulse; obstinate vomiting, particularly of a greenish fluid; singultus, continued or recurrent; the rapid healing of chronic ulcers; the appearance of the disease in the course of other maladies, particularly pneumonia, the exanthemata, and after apoplexy, and in the scrofulous habit, or in persons having an hereditary disposition to cerebral affections, or who have been recently affected by other maladies.

189. *c.* The disease may pass into an obscurely chronic form, which together with the effects produced by its antecedent state, may give rise to paralysis, epilepsy, various states of mania or mental disturbance, idiocy, &c. In these cases, many of the chronic changes which have been described as occasionally found in either the membranes or the substance of the brain, particularly those which affect parts only of these structures, have taken place, as softening, abscess, induration, tumours, ossific formations, &c. (§ 50. 71. 102, &c.).

190. *d.* When encephalitis arises from *rheumatism* (*Encephalitis Rheumatica*, J. FRANK), the membranes, particularly the dura mater and arachnoid, are chiefly affected; and the danger has been considered, upon the whole, less than in other states or relations of the disease. The disposition, however, to effusion, and to many of the chronic organic changes described as frequently found in the membranes, is great. It often assumes a sub-acute or chronic form, and is usually attended with great distress, but is without delirium. The *gouty form* of encephalitis generally is observed in older persons than the rheumatic; is accompanied with much disorder of the stomach, liver, and bowels, and with deficient vital power; and is hence a more dangerous state of the disease. The same remark is applicable to its occurrence from the extension or suppression of *crispelatus*. In these, the re-appearance of rheumatism or gout in a joint or extremity; the eruption of the crispelatus inflammation in any part of the surface, even in the face (J. P. FRANK); the supervention of diarrhœa, the hæmorrhoidal flux, or any other discharge; are favourable circumstances. Encephalitis, occurring after the disappearance of the eruption in the exanthemata, or during the course of typhoid or epidemic fevers, or pulmonary diseases, or after attacks of apoplexy, paralysis, epilepsy, or mania, is much more dangerous than when appearing in a primary form, owing, 1st, to the depressing of the vital and nervous powers; 2d, to the vitiated state of the circulating fluids; and, 3d, to the silent and insidious manner in which the disease of the brain often advances to disorganisation in these complications. According to HUFELAND, encephalitis, supervening on the disappearance of the variolous eruption, is generally fatal. The *alterations of structure occasioned by encephalitis* are fully described in preceding sections of this article (§ 11. *et seq.*).

191. VI. TREATMENT. — *A.* Of the *idiopathic and simple encephalitis*. It must be evident that the treatment should be the same, whether the membranes or the substance of the brain be chiefly, or entirely, the seat of disease. The

causes, the age, the habit of body, and apparent state of vital power, are circumstances which ought to be duly considered when adopting the means of cure, or determining upon the extent to which they ought to be carried. *a.* The *antiphlogistic treatment*, in all its departments, must be rigorously enforced. Some discretion is, however, required as to the extent to which it should be carried, and the direction, choice, and adaptation of the individual means of which it consists. In ordinary cases, bleeding from the jugular vein; cupping between the shoulders, nape of the neck, behind the ears, or occiput; leeches applied in those latter situations, and bleeding from the arm, are upon the whole the preferable modes. Arteriotomy I consider to be attended with no advantages; and in this I am supported by the opinion of HILDENBRAND and others; but bleeding from the feet, from the hæmorrhoidal vessels, and from the groins and insides of the thighs, are undoubtedly preferable when the disease arises from metastasis or the interruption of discharges, especially when conjoined with the treatment I shall presently describe as appropriate to those states. HILDENBRAND, and several other German physicians, recommend the application of leeches to the insides of the nostrils, when the patient has been subject to epistaxis, or if a disposition to critical epistaxis be evinced. As to the extent to which depletion should be carried, no precise opinion can be given. It should be regulated according to the circumstances of the case, and its effects upon the circulation, and be conducted in the manner I have recommended in the article on the *Pathology of the Blood* (§ 64.). It ought never to be relied on alone: other means should be simultaneously, or subsequently employed, with the view of diminishing local and general action, and thereby preventing the removal of more blood than may be indispensable.

192. *b.* The hair should be removed from the head as soon as possible, and a *stream of cold water* poured upon it from time to time, or every second or third hour, until the temperature be reduced to the natural standard; and, as morbid heat soon returns, *cold epithems*, or evaporating lotions, or even pounded ice enclosed in a bladder, should be constantly applied in the intervals between the *cold affusions*, and the head be kept elevated, and placed upon a thick oil-skin, or, what is still better, upon a piece of common painted floorcloth, as long as increased action continues. Cold applications or affusions may, however, be injurious if too long persisted in. They ought never to be continued after the temperature is depressed to the natural standard, or a little below it, particularly if sopor or coma be present; and as soon as the heat returns, they should be again resumed. Simultaneously with the affusion, the feet and legs should be immersed in warm water, or in warm water made irritating by means of salt and mustard, and the saphena vein be opened. In some cases, particularly when suppression of the menstrual or hæmorrhoidal discharge has preceded the attack, *semicupium* or *hip-bath*, may be substituted for pediluvium.

193. *c.* The immediate exhibition of *cathartics* should not be neglected. From ten to twenty grains of calomel may be given at once, and three or four hours afterwards, an active purgative

draught, which should be followed by cathartic enemata, particularly the *En. Cathart.* and the *En. Terebinth.* (F. 141. and 150). By these, or similar means, a copious action of the bowels should be procured and continued. With this latter intention, pills calculated to promote the abdominal secretions may be given each night, a purgative draught the following morning, and an enema subsequently, if it be necessary. Calomel combined with digitalis, or with antimony, should be prescribed in full and frequent doses, in addition to the above, so as to change the state of morbid action, particularly when the membranes are chiefly affected. The following, or similar medicines, may be used, and their effects carefully watched:—

No. 55. R. Calomel. gr. iij.—x.; Pulv. Jacobi Veri gr. iij.; Pulv. Digitalis (vel Pulv. Colchici) gr. j.—ij.; Syrup. Simp. q. s. M. Fiat Pulvæ iij. vel iij. tertiâ, quintâ, vel sextâ quaque horâ porrigende.

No. 56. R. Hydrag. Chloridi gr. iij.—vj.; Pulv. Jacobi Veri gr. iij.—vj.; Extr. Colocynth. Comp. gr. vj.; Syrup. Simp. q. s. Fiat Pulvæ iij. horâ somni sumendus.

No. 57. R. Infusi Senæ Comp. ʒjss.; Magnes. Sulphatis ʒij. (vel Potassæ Tart. ʒjss.); Vini Antimon. Pot-Tart. ʒss.; Tinct. Jalap. ʒj. Tinct. Cardam. Co. ʒj. M. Fiat Haustus, primo mane sumendus.

194. d. In addition to these means, the frequent exhibition of *refrigerants* and *saline medicines*, especially those consisting of the *liquor ammon. acet.*, *potassæ nit.*, *antimonials*, &c., will be of much service. The preparations of antimony, judiciously exhibited, have a remarkable influence in diminishing determination of blood to, and inflammatory action in, the brain; and I believe that the effect will be more decidedly beneficial, if their operation as an emetic be carefully avoided. Form. 24. 359. 406. 436. 456. and 854. are of the above description, and, as well as others of a refrigerant and diaphoretic nature, may be employed, in small or moderate and frequently repeated doses. I may state, as the result of considerable experience, that I have found the *saline refrigerants* and *antimonials* most beneficial during the early stage of the disease, and where the membranes were chiefly inflamed. In the stage of coma, or when the substance of the brain itself is affected, and the pulse is quick, weak, small, trembling, or irregular, antimonials are not admissible; the preparations of *camphor*, with *liquor ammon. acet.* and *spirit. ather. nit.*, being preferable. (See F. 405. 436. 441.)

195. e. *Sedative* and *diuretic* medicines, particularly *colchicum* and *digitalis*, combined with the *liquor ammoniæ acet.* and moderate doses of *camphor* (F. 395. 400. 514.), are extremely useful in the early stage of the disease, after depletion and the free evacuation of the bowels. In the advanced stage, however, much less advantage will be derived from them. After blood-letting has been carried as far as may be thought judicious, and if much restlessness and jactitation be present, great advantage will be derived from the exhibition of a moderate dose of *camphor*, *hyoscyamus* and *James's powder*, in this or any other appropriate form:—

No. 58. R. Pulv. Jacobi Veri gr. iij.—v.; Camphoræ rasæ gr. ij.—iv.; Extr. Hyoscyami gr. iv.—viij.; Syr. Papav. q. s. ut fiat Pulvæ iij. statim sumendâ et h. s. retinendâ.

No. 59. R. Mist. Camphoræ ʒj.; Liq. Ammon. Acet. ʒij.; Spirit. Ether. Nit. ʒss.; Tinct. Colchici Semin. ʒij. —xx.; Syrupi Papaveris ʒj. Fiat Haustus, tertiis vel quartis h. ris capiendus.

196. f. *Derivatives* and *counter-irritants* are useful in many cases, when judiciously prescribed. In the early stage of the disease, and whilst great irritability or delirium is present, they are often prejudicial, excepting simple pediluvia, the semicupium and hip-bath, employed simultaneously with cold applications to the head. Great mischief has arisen from ordering blisters and mustard poultices too early in inflammations, but more particularly in encephalitis, when, instead of deriving the circulation from the inflamed part, they excite the nervous and vascular systems generally, and thus react upon the disease. It is chiefly in the latter stage, when sopor or coma is present, that benefit is derived from them. Some difference of opinion has existed as to the part to which they—particularly blisters—ought to be applied. If the coma be profound, some writers have advocated the application of blisters directly to the scalp. Without denying the possibility of circumstances arising to justify this practice, I believe that they will seldom occur. The most profound sopor, weak action of the carotids, a not remarkably frequent pulse, and a temperature of the head much and permanently below the natural standard, would only induce me to apply blisters to the scalp. When *derivation* can be attempted with safety,—when sopor is present, and morbid sensibility and irritability has nearly disappeared, and depletion has been carried as far as seems judicious,—a large blister to the nape of the neck or between the shoulders, or over the epigastrium, mustard poultices to the insides of the legs or thighs, or irritating liniments (see the *Liniments* in the Appendix) in the latter situations, will often be used with advantage. The *semicupium*, *warm bath*, or *pediluvia*, are seldom of service when there is much general febrile excitement, particularly in children, unless when used simultaneously with cold affusion on the head. But when the lower parts of the body have their temperature reduced below the natural standard, and when the disease has appeared after suppressed discharges, &c., they are often of service, and may be made more *revulsive* by salt or mustard.

197. g. Various remedies have been recommended in the treatment of this disease, in a more particular manner than others. Amongst these, the most generally employed and most beneficial is *calomel*, when given in large and repeated doses, and judiciously combined, and until an impression is made upon the disease, or state of the circulation. In the *meningitis* of children, this practice is particularly requisite, as, without it, but little impression will often be made on the disease; and, with due attention, but little risk will be run of experiencing unpleasant results from it. Where we dread impending exhaustion, the calomel may be combined with small doses of *camphor* and *ammonia*, and a less restricted regimen allowed. MARCUS recommends strongly very large doses of *nitre*, which may be combined with antimony, or with diuretics; HEDGEMAN, the preparations of *mercury* carried to the extent of salivation; CHAUSSIER, the *boracic acid*, very nearly as prescribed in F. 343.; several physicians in Italy and in Switzerland, especially BRERA, TOMMASINI, PESCHIER, LAENNEC, &c., large and frequently repeated doses of the *potassio-tartrate of antimony* so as to act upon the bowels;

LOEFFLER (*Hufeland's Journ. der Pract. Arzneik.* b. iii. p. 694.), free incisions of the scalp; and ARRETEUS (*Curat. Acut. l. i. ch. 1.*), CÆLIUS AURELIANUS (p. 30.), and ZACUTUS LUSTANUS (*Med. Pr. Hist. l. i. p. 85.*), scarifications and cupping in the same situation. All these are undoubtedly advantageous, when judiciously prescribed. Besides these there are remedies which are very generally employed, and which are beneficial in certain states of the disease only; these are, camphor, digitalis, hyoscyamus, opium, &c. In the early stage, camphor, unless in very minute doses, is prejudicial; but when sopor or coma is present, when depletion has been duly practised, the heat of the head has subsided, the energies of life are depressed or exhausted, and the symptoms are apparently the consequence of the lost tone of capillaries of the brain, moderate and frequently repeated doses of this medicine are almost indispensable; particularly in the complications of the disease with typhus, or epidemic fevers, with gout or rheumatism. *Digitalis* as well as *colchicum* are principally required in the early stage, when either of them may be combined with *calomel*: if exhibited subsequently, they should be given with camphor, and their effects carefully watched. Both these medicines may be advantageously combined with aperients or with diuretics. BRERA recommends digitalis as follows in the earlier stages of the disease:—

No. 60. R. Pulv. Fol. Digitalis gr. xvj.; Hydrarg. Chloridi gr. x.; Pulv. Rad. Glycyrrh. ℥j.; Olei Junip. q. s. M. Fiat Pulv. viij. Capiat binas tertius vel quartis horis.

The combination of camphor with *colchicum* is often of service in the *gouty* and *rheumatic* forms of the disease. I found it recently of much advantage in a severe case of the latter.

198. *Narcotics* ought generally to be avoided; yet there are states of the disease, chiefly in adult and aged subjects, which are benefited by them. When lethargy or coma, or an obvious disposition to either, is present, narcotics are injurious, particularly in cerebritis; but when the membranes are obviously most affected, and the disease presents much of the phrenitic character; when great irritability, mental excitement, or exhausting watchfulness is present, particularly after depletions and other evacuations have been carried as far as seems judicious, and the pulse has been reduced, or become less febrile; a full dose of *hyoscyamus*, or even the preparations of *opium*, particularly the acetate or hydro-chlorate of *morphia* (F. 315. 674.), the compound tincture of *opium* (F. 728, 729.), or *Batley's* sedative liquor, may be exhibited. In cases where the propriety of having recourse to these medicines admits of doubt, they should be combined with moderate or full doses of *camphor* (F. 554. 787.), or the *Spiritus Æther. Sulph. Comp.* (F. 375.)

No. 61. R. Camphoræ rasæ gr. j.—iv.; Gum. Acaciæ, Sacchari Albi. aa ʒ ss.; Magnes. Carb. ℥j.; Decocti Althææ ʒjss.; Spirit. Æther. Sulph. Comp.; Tinct. Hyoscyami, aa ʒj. (vel Tinct. Opii Comp. F. 729. ʒ ss.) M. Fiat Haustus.

199. *B. Treatment of the complicated states.*—There are certain consecutive and complicated forms of the disease which require a somewhat modified treatment.—*a.* The *rheumatic* encephalitis, according to J. FRANK, does not admit of cold applications to the head; in other respects,

the means of cure do not differ from those already stated. I believe that, in its advanced stage, the application of a blister to the scalp is more likely to be of service in this than in any other form of the disease; and the same remark may be extended to the use of *colchicum* and *camphor*—the latter of which may sometimes be advantageously combined with the potassio-tartrate of antimony or James's powder.

200. *b.* In the *arthritic* complication, after general and local depletions,—the latter chiefly on the right hypochondrium, hæmorrhoidal vessels, and insides of the legs,—followed by active purging, stimulating and irritating pediluvia, sinapisms and blisters applied to the lower extremities, and *colchicum* combined with the carbonates of the fixed alkalies, and diuretics, are chiefly indicated.

201. *c.* When encephalitis occurs in the *course of fevers*, or when it is seated chiefly in the substance of the brain, and assumes a *typhoid* character, from the depressed state of the vital powers, either at the commencement or in consequence of treatment, the infusions or decoctions of *arnica*, *senega*, or *serpentaria*, have been recommended by the German writers, after depletions have been carried as far as seems prudent. When the disease is thus complicated, depletions should be employed with caution; and those which are local and derivative ought to be preferred, *revulsants* being simultaneously prescribed; cold applications to the head require equal caution. In the early stage of this complication, J. FRANK recommends a combination of *camphor*, *cinnabar*, and *nitre*, every two hours. The first of these is amongst the best medicines we possess in every stage of such cases; but it should, in the advanced periods, be exhibited in larger doses than early in the disease; and it may often be advantageously combined with *calomel*. A similar treatment is applicable when the disease appears in the course of *bronchitis* and other pulmonary diseases.

202. *d.* The *erysipelatous* complication of encephalitis often requires a more antiphlogistic and depletory treatment than the typhoid form of the disease; but such is not uniformly the case. I conceive that deep and large incisions into the scalp, particularly over the occiput, as recommended by LOEFFLER, would be more applicable to this state of the malady than to any other, especially if there be much tumefaction of the scalp or countenance. When encephalitis follows, or is complicated with *apoplexy*, the treatment differs in no respect from that which has been recommended for the primary form of the disease. Incisions or scarifications of the scalp may be also practised in this complication.

203. *e.* The supervention of encephalitis in inflammations of the digestive mucous surface is not infrequent in children: and in diseases of the liver in persons of middle age, or advanced in life. In these cases the treatment is not materially different from that already advised. Local depletions over the region of the liver; full doses of *calomel*, so as to affect the mouth; cold affusions on the head, particularly in the former state of complication; external and internal *revulsants* and diuretics; are generally indicated.

204. *f.* The appearance of the disease after *irritating* and *narcotic poisons*, particularly after *opium*, *aconitum*, *belladonna*, &c., is not infre-

quent. These occasion, first, congestion, and afterwards inflammatory action. In encephalitis from these substances, vascular depletions, cold affusion on the head; emetics, or the introduction of the stomach-pump; camphor or arnica, combined with antimonials or aperients; external derivatives, and active purging, are amongst the chief means of cure.

205. *C. Of the treatment of the more unfavourable and anomalous states of the disease.*—The practitioner, although he will very frequently, or even generally, find the treatment described above successful, may sometimes meet with cases in which the symptoms persist, notwithstanding repeated depletions, and the other remedies prescribed; the energies of life being more or less depressed; the pulse becoming very rapid, irregular, trembling; the coma or stupor more profound, and the temperature, even of the head, much diminished. He may or may not have had recourse to derivatives, but in either case they may be continued or varied; and camphor, musk, valerian, ammonia, HOFFMANN'S anodyne, and other restorative medicines, variously combined, may be exhibited. If the pulsation of the carotids and temperature of the head be not in such cases increased—or if they be diminished, and the energies of life be obviously depressed or exhausted, both in the affected organ and throughout the system—the above diffusible stimulants will often be inefficacious. In this case, the infusion of the flowers of arnica, or the infusion of serpentaria, either simply or combined with cinchona; camphor, in larger doses, and given occasionally with calomel and small doses of opium; active frictions of the surface and lower extremities with rubefacient liniments, and in some instances, particularly if effusions between the membranes be suspected, with mercurial liniments, or inunction of the scalp, are the principal means that can be adopted. But if, notwithstanding those, the above symptoms continue or increase,—the evacuations being involuntary, and the patient unconscious of them; a vomiting, or rather a pumping up, of whatever is taken into the stomach, with singultus and an intermitting, trembling pulse, that cannot be distinctly counted, being also present,—are we to continue to give the medicines which we have found inefficacious, thus leaving the patient to his fate, or are we to resort to still more active means? There can surely be no hesitation as to the part which ought to be taken. In a case of this description, consecutive of bronchitis, in a robust man of middle age, who was attended by Mr. FAXON, Dr. BREE, and myself, after depletions and cold applications had been carried as far as it was judged prudent, and blisters were applied on the epigastrium and nape of the neck, without benefit, full doses of calomel and camphor were given, the following medicines prescribed, and their action promoted by the enema terebinth. (F. 151.) :—

No. 62. R. Camphoræ rasæ gr. iij.; Ammoniaë Sesqui-Carbon. gr. iv.; Mucilag. Acaciaë q. s. Piant. Pilulæ ij., omni secundâ horâ, cum Haustu sequente, sumendæ.
No. 63. R. Mist. Camphoræ ʒj.; Liq. Ammon. Acet. ʒijss.; Spirit. Æther. Sulph. Comp. ʒss.; Tinct. Capsici ʒiij.; Syrup. Croci ʒss. M.

The following draught was also given, four hours after the exhibition of a large dose of calomel and camphor, with the view of deriving the circulation from the head, and of acting

decidedly on the abdominal secretions; and was repeated every hour until three were taken.

No. 64. R. Olei Terebinth., Olei Ricini. aâ ʒij.; Tinct. Capsici ʒiij.; Olei Cajuputi ʒvi.; Aquæ Menth. Virid. ʒjss. M.

The pulse soon afterwards became more distinct and regular, the bloated cast of countenance subsided, and all the symptoms improved. The patient afterwards quickly recovered, and is now in perfect health. At the time the above treatment was suggested by me, his recovery was considered almost impossible. Several years ago, I was consulted by Mr. HARRY COX respecting a very similar case, which was consecutive of erysipelas. In this a similar treatment to that now noticed was adopted, and the patient recovered from an extreme state of danger. This case is published in the twenty-third volume of the *London Medical Repository*. In those states of the disease which are characterised by profound sopor, depression of vital power, and the symptoms above referred to (§§ 180. 205.), other means having proved insufficient, a judicious exhibition of the oleum terebinthinæ has very frequently a decidedly beneficial effect, particularly in the typhoid, erysipelatous, and other complications of the disease; and, when suitably prescribed, will generally allay the irritable state of the stomach, with which the worst forms of the malady are often attended even during their advanced stages.

206. The experienced practitioner should be aware that the existence of profound sopor or coma does not contra-indicate sanguineous depletions or cold applications to the head, if conjoined with this state, the temperature of the head be at all increased, or the pulsations of the carotids strong or full. If these evidences of increased action be present, those important parts of the treatment ought not to be omitted; but the depletions should often be moderate or local merely; and, in my opinion, preferably from the scalp of the occiput or nape of the neck, by cupping, or by deep incisions of the former. When the disease is consequent upon suppressed discharges, a derivative intention may be had in view, and the lower extremities, the groins, the vicinity of the anus, &c., may be selected as the situations for depletion. In *traumatic encephalitis*, the fact that the disease either does not appear whilst the wound in the scalp remains open, or is averted by a long-continued discharge from it; and that the worst states of cerebritis often arise after injuries of the head, when the external wound has readily and prematurely healed, furnish a striking indication of the propriety of having recourse to incisions of the scalp in the other forms of the disease, and to issues and setons in the same situation subsequently, when their sequelæ indicate the propriety of having recourse to permanent irritation, with puriform discharge, for their removal.

207. *D. Treatment of the sub-acute and chronic states of encephalitis, particularly in children.*—*a.* One of the most frequent forms of sub-acute inflammation of the brain is observed in *infants*, principally affecting the substance of the organ, and often terminating in dropsy of the ventricles. It is chiefly characterised by want of animation, by slight sopor, indifference to all objects, absence of sound sleep, and a state that is different from waking. The child is dull, but fretful and irri-

table upon being roused or handled. The head generally droops, or reclines on one side; the countenance is usually pallid, but occasionally irregularly flushed; the eyes are dull, rolled about, or turned up; the pupils sometimes dilated, at other times contracted; and the infant often utters a plaintive moaning, and occasionally starts soon after having fallen asleep, as if pained or frightened. The hands are tossed about or raised to the head; the lower extremities alternately extended and drawn up to the abdomen; the head thrown backwards; and occasionally its temperature is slightly increased, whilst the heat of the rest of the body is either natural, or somewhat diminished. This grade of disease may continue for a long time; sometimes fluctuating, at other times passing into either a more acute or more chronic form, or at last terminating in dropsy; the bowels being either relaxed or irregular, but in either case with a morbid and offensive state of the motions. The shades of difference observed in this form of disease are numerous: the pulse is very variable, as well as the appearance of the tongue; which is, however, most frequently red at its point and edges, and white or loaded at its middle and base: in some of the more chronic cases, particularly when the disease is complicated with chronic disorder of the digestive mucous surface, it has what may be called a strawberry appearance, from the number of bright red dots scattered over it. This variety of the disease is often associated with torpor or imperfect function of the liver, with disease of the mucous surface of the stomach or bowels, or with both; and occasionally with bronchitis, especially during the period of dentition, when it often supervenes.

208. *b.* Another variety of this affection is also frequent in infants and children, and seems to be chiefly seated in the arachnoid. Dr. W. NICHOLLS has termed it sensitive erethism of the brain. It is characterised by a morbidly increased sensibility, which distinguishes it from the foregoing variety. The child often cries without any obvious reason; is generally wakeful, lively, but irritable; all the senses, even that of touch, are morbidly acute, particularly the senses of sight and hearing: it frowns, winks its eyes, or closes them upon exposure to light; it sometimes shrieks, clenches its hands with the thumb bent across the palms, tosses backwards its head, and presents many of the symptoms of the preceding form of disease; and not infrequently terminates in effusion; but, more frequently than the foregoing, between the membranes exterior to the hemispheres.

209. *c.* The Treatment chiefly consists of leeching behind the ears or on the occiput; frequent scarifications of the gums; the affusion of cold water on the head, or cold sponging; calomel purges, followed by castor oil or other cathartics, and occasionally promoted by terebinthinate enemata; frequent warm semicupia; the use of saline aperients combined with diuretics, and strict attention to diet and regimen, with change of air. After the several active calomel purges have been exhibited, and the evacuations have improved, and the more obvious symptoms are abated, small doses of hydrarg. cum cretâ may be given at night, either alone or combined with a little of the carbonate of soda or potash, and a

weak saline mixture through the day, similar to the following, or to F. 440. and 441.

No. 65. B. Magnesie Sulphatis (vel Sodæ Sulph.) ʒij; Potassæ Sulphatis ʒj.; Aquæ Fœniculi ʒivss.; Spirit. Æther. Nit., Vinii Antimonii Pot. Tart., Spirit. Juniper. Co., aa ʒj.; Syrupi Scillæ ʒij. M. Capiat Infans ʒj.— ʒij. ter quaterve quotidie.

210. When the morbid sensibility or irritability continue, notwithstanding the above treatment, and if the child be not very young, small doses of James's power, and, if that fail of procuring quiet, of the pulv. ipecacuan. comp. may be conjoined with the hydr. cum cretâ, and given every night; or a little tinct. of hyoscyam., or of the extr. conii, may be added to the above mixture. In the soporose form of the affection, narcotics must be avoided, but the rest of the treatment strictly adhered to. Small doses of camphor and nitrate of potash may also be exhibited,—if in solution, with the spirit. æther. nit., and blisters applied either to the nape of the neck, or behind the ears, or turpentine epithems over the shaved scalp.

211. *E. Treatment of the sequela of encephalitis.*—After an attack of this disease, the patient may complain of vertigo, more or less torpor or weakness of the mental powers, cephalalgia, &c.; or of increased sensibility, and marked erethism of the brain and whole nervous system, watchfulness, incapacity for mental exertion, tinnitus aurium, languor, and pain in the limbs, &c. In all such or similar cases, the diet should be carefully restricted to food of easy digestion, in moderate quantity, and consisting chiefly of the farinaceæ. Change of air, easy travelling, avoidance of all mental exertion and anxiety, and attention to the secreting and excreting functions of the abdominal viscera and of the skin, will generally bring about perfect recovery. If these fail; or if the patient have irregular flushings, or increased heat of head; or if the carotids pulsate more strongly than usual; the shower-bath, cold sponging the head night and morning, and wearing the hair closely cut, occasional local depletions, the insertion of a seton in the neck; or keeping out an eruption, in the same situation, with the tartarised antimonial ointment; or blisters kept open behind the ears for some time; may be prescribed.

212. When the more severe sequela of the disease are present,—such as cramps, pains, or spasms of the extremities, hebetude or derangement of the mental faculties, obstinate headach, &c.,—we should suspect the existence of a chronic state of the disease, and resort to occasional local depletions, cold affusions, or sponging of the head; followed by issues in the scalp of the occiput, or the inunction of the tataric emetic ointment in this situation; and to the mercurial preparation at bed-time, with cooling and deobstruent aperients on the following morning; and to the other means above recommended. When we apprehend, from the marked character of the above symptoms, or from the paralysed state of particular muscles or parts, that organic lesion has been produced, the means now recommended should be strenuously persisted in; and the mercurial medicines may be pushed to slight salivation, under the favourable circumstances of pure air and mental quiet; after which, gentle tonics, and a more invigorating treatment and regimen, may be cautiously tried.

213. *F. The regimen during the disease should be strictly antiphlogistic.* The patient's drink or beverage may consist of either of the formulae,

No. 590—595. 915. contained in the Appendix ; and attention should be paid to the state of the urinary discharge ; particularly to the prevention of accumulations of urine in the bladder, which ought to be removed by the catheter whenever any interruption of its evacuation occurs. The diet, and regimen generally, should be as carefully regulated during convalescence, as in the progress of the disease ; and attention ought to be directed no less to the mental occupations, and moral emotions, than to the natural functions, and physical employments. Care should be taken not to carry abstinence too far in the meningitis or encephalitis of infants or children, particularly after large sanguineous depletions and doses of calomel have been employed. The exhaustion arising from too great abstinence, and from the treatment, will often simulate effusion into the ventricles ; and be mistaken for it, if the history of the case be not carefully attended to in connection with existing symptoms.

BRAIN — SOFTENING OF THE. — *Ramollissement*,
Fr. — CLASSIF. IV. CLASS, IV. ORDER
(Author, see Preface).

214. I have considered this change, apart from those proceeding from inflammation, although it is frequently a consequence of inflammatory action, occurring either in an acute, sub-acute, or chronic form, and characterised by deficient vital power ; chiefly because I agree with M. M. ROSTAN, RECAMIER, and others, in considering that it occasionally is unconnected with inflammation, particularly in aged persons.

215. i. SYMPTOMS. — This disease takes place slowly, and we may distinguish in it two stages the recognition of which is of much importance in the diagnosis, inasmuch as when the first period does not exist, or when the physician cannot obtain a satisfactory knowledge of it, it is difficult to determine the particular kind of disease present. 1st. *The first period.* — *A. Direct symptoms*, *a. of non-inflammatory softening.* — A continued, and more or less severe, pain in the head is generally complained of. To some, the existence of pain may appear pathognomonic of inflammation ; but, as M. ROSTAN has justly said, this is an inference not borne out by close observation ; for pains frequently occur, of a most severe description, unconnected with any form of increased vascular action, or capillary injection. Cephalalgia is, however, not always present. At this period, vertigo is oftener complained of, and there is generally a more or less marked diminution of the intellectual and moral faculties. The perceptions, attention, judgment, memory, and imagination, are more or less enfeebled ; and the patient sinks into a species of senile mental alienation. Sometimes the mental disturbance is partial or slight, owing to the seat and limited extent of the softening. There are observed, moreover, slowness in the answers ; some degree of embarrassment in the motions of the tongue ; dejection and sadness of spirits ; hypochondriasis, or an extreme indifference as to events ; great inclination to sleep, with prickings, twitchings, and numbness in the limbs ; and much difficulty of laying hold of objects, particularly those of small size. The sensibility is generally diminished ; vision is often affected, being less distinct than usual, or partially or altogether abolished. It very rarely happens, that unequal dilatation of the

pupils, or strabismus, occurs. The sense of hearing is generally impaired. These are the chief symptoms of *non-inflammatory* softening of the brain.

216. *b.* If the *softening* proceeds from *inflammatory action*, this period is more acute, of longer duration, and presents also certain important distinctions. The pain in the head is then more acute and sharp ; the answers are abrupt and quick, and there is frequently delirium : the sensibility of the limbs is often increased, and the patient complains of pain in them, with stiffness, contractions, and cramps. This affection of the limbs may be mistaken for rheumatism, but is to be distinguished from it by the existence of cerebral symptoms, and the absence of increased heat, redness, or tumefaction. The senses evince excessive sensibility, and cannot tolerate their natural stimuli. (ROSTAN.)

217. *B. Indirect symptoms.* — *a.* The functions of organic life do not present undeviating symptoms, and assist but little the diagnosis ; the appetite may be diminished, the thirst somewhat increased, and digestion more or less disturbed, and the mouth and tongue white and clammy. Sometimes there is nausea, or even vomiting, with epigastric tenderness ; and there may be either constipation or slight diarrhoea ; micturition is more or less difficult, or involuntary ; or all these symptoms may be absent. The following are more constant in this non-inflammatory form of the disease : the pulse is slower and feebler than natural, a symptom which is not observed in inflammatory softening of the brain ; the skin is pale, its temperature is lower than natural, and the respiration slow and gentle. *b.* In *inflammatory softening* the pulse is strong, full, or frequent ; skin hot ; and there is much thirst, with many of the symptoms described in the section on *Cerebritis* (§ 164.), but generally in a sub-acute or chronic and slight form. Thus far, the symptoms do not seem very urgent ; and they may be so slight, or so obscure, that the patient is not induced to have recourse to medical aid, or the physician overlooks the nature of his ailments.

218. 2d. *Second period.* — *A. Direct symptoms.* — *a.* The patient now loses the use of some limb, or even one half of the body, either gradually or suddenly, but generally the latter. The greater part of the time his intelligence is but little disturbed, but he answers with extreme slowness, and is often incapable of making himself understood, excepting by the aid of painful gesticulation. In certain cases, either complete coma supervenes on the paralysis, or both come on simultaneously. If the latter, the patient often regains his recollection in a day or two afterwards. This change seems attributable to temporary congestion of the brain. The symptoms, particularly the coma and paralysis, are increased, the mental faculties and the powers of sense become entirely abolished, and the patient sinks under the most complete coma. (ROSTAN.)

219. *b.* In the *inflammatory softening*, in the place of paralysis, there exist pains, more or less violent, shootings in the limbs, with contractions, cramps, or convulsions, and severe headach. In either the inflammatory or non-inflammatory form of the disease, when the patient complains of pain in the head, and is asked its situation, he carries the unaffected hand slowly to his head, and indicates generally the side opposite to that paralysed. In *encephalitis*, there is generally the

delirium; in the *non-inflammatory* form of softening, the intellectual faculties are enfeebled, or much weakened; the countenance is generally pale, colourless, or sometimes even sunk; whereas in *inflammatory softening* it is red, or more or less injected, or even tumid.

220. *B. Indirect symptoms.*—*a.* In this second stage of the disease, the organic functions are more or less affected: there is no appetite; the teeth and gums are dry, the tongue rough, brown, blackish, chopped or traversed by small fissures; deglutition is difficult: sometimes there is vomiting, first of the ingesta, and afterwards of bile: all the excretions are involuntary; frequently there is constipation: respiration is laboured, and at last stertorous: the pulse feeble, frequently irregular or unequal, or even intermittent, and the skin is cold. *b.* In *inflammatory softening* there is great thirst, redness of the tongue, sensibility of the epigastrium and abdomen, hot skin, a strong and frequent pulse, &c. (See § 170.)

221. The second period may be of longer or shorter duration. The morbid phenomena often continue stationary for a considerable period, and then make rapid progress; at other times the progress is slight, but constant; in some cases it is constant and remarkable. This disease very rarely retrogrades or evinces much amelioration; its progress is essentially continued and increasing. The *anatomical characters* of softening have been already fully described (§ 70, et seq.). It may be stated in general, that when it is the result of inflammatory action, as it most frequently is, 1st, The colour of the softened part is, more or less, deeper than natural, or of a rose tint; 2d, It contains a certain quantity of pus, sometimes infiltrated through the softened tissue; and, 3d, Febrile symptoms have existed previously to the death of the patient.

222. *ii. TREATMENT.*—It is unnecessary to add any thing to what has been already advanced respecting the treatment of the inflammatory states of softening, which are essentially the consequence of partial cerebritis (see § 191, et seq.). When, however, the disease does not present an inflammatory character, it becomes necessary, not only to enjoin abstinence from all debilitating means, but from the commencement to apply rubefacients, to throw irritants into the great intestines (see *Enem.* F. 141. 150.), and to have recourse to tonics, aromatics, &c., of which the sulphates of zinc, iron, or quinine, in small doses, with sulphuric acid, or the less heating astringent tonics belonging to the vegetable kingdom, are the most eligible; preserving, at the same time, a regular state of the alvine secretions and evacuations, and of the other digestive functions.

223. *Regimen.*—The gently tonic, chalybeate, and aperient mineral waters are of service in the non-inflammatory form of the disease; whilst those only which are aperient and deobstruent should be ventured upon in its inflammatory states, when they may be tried and varied; local evacuations, revulsives, particularly setons, issues, &c., being kept discharging at the same time. In both forms of the disease, gentle travelling, and change of air, and agreeable and quiet amusement, without undue mental excitement of any kind, will be of much service. M. ROSTAN'S injunctions under this head may be summed up as follows:—Those alimentary and medicinal sub-

stances which exert a strong and speedy action on the encephalon, should be strictly shunned. Wine, spirits, coffee, and spices, are of this number. Excess at the table is dangerous. The diet should be mild and moderate, and the food easy of digestion, but not too nutritious. The impression of cold air on the head may be favourable: sudden passage into a heated place must be avoided: the patient should inhabit a cool situation. Whatever, by compressing the limbs or the organs contained in cavities, may favour cerebral congestion, must be rigidly proscribed. Warm, as well as cold bathing, should be interdicted: tepid bathing alone may be permitted, although with much caution. Cold lotions to the head are advantageous in the inflammatory form of the disease, provided we do not permit reaction to be established; at the same time pediluvia containing mustard may be prescribed. The ordinary excretions should be kept up; but sexual indulgence, too violent exercise, strong emotions, long study, and watchings, should be carefully avoided. The age, strength, constitution, habits, and state of the patient, and the character of the symptoms, must modify these precepts.

BRONCHI, DISEASES OF THE.—*SYN.* Βρόγχος, Gr. *Bronchus*, *Bronchia*, Lat. *Bronche*, Fr. *Die Luftröhrenäste*, Ger. *Bronchi*, Ital. *Air-passages*, *Air-tubes*, Eng.

1. BRONCHI AND AIR-TUBES.—*Their Alterations.* Under this head, the alterations of structure usually found in the air-tubes, from the larynx to the smallest subdivisions of the bronchi will be first considered, and subsequently the history of such of them as are more immediately seated in the bronchi, and are not treated under distinct heads, where some of them are placed, owing to their specific nature, and their relations to other parts.

2. I. ALTERATIONS OF STRUCTURE IN THE BRONCHI.—As the same lesions are found in the larynx and trachea, as in the bronchi, although certain of them are more frequent in one part than in another, no particular distinction depending on locality merely will be made, in order that repetitions may be avoided.

3. i. ALTERATIONS OF THE MUCOUS MEMBRANE OF THE AIR-PASSAGES.—These are the same in kind from the glottis to the air-cells, whether the vascularity, the structure, or the secretions of this membrane, be individually or collectively changed.

A. Passive or simple congestion of this surface is not unfrequently found after death; and there is every reason to believe that it may take place during life, or at the moment of death, or even be a *post mortem* change. When occurring during life, it is most frequently met with in the debilitated, and when the return of blood to the left side of the heart has been impeded. Simple congestion of this membrane may be either partial or general. When *general*, and at the same time suddenly and intensely formed, it may terminate life with all the symptoms of asphyxy. (*See CONGESTION OF THE BRONCHI.*) In a slighter form it accompanies various diseases, particularly the febrile exanthemata; but it is seldom found in a chronic form. Congestion of this membrane

presents various depths of shade, varying from a dirty pale red, or a brick red, to a brownish or purplish hue; being sometimes equally deep throughout, in others of a different shade in different situations.

4. *B. Inflammatory injection*, or active congestion of the bronchial surface, is generally *partial*, or affects one part of the air-passages more than another. It is also of a livelier colour, and is usually attended with some of the changes hereafter to be noticed. Partial or inflammatory redness of the mucous membrane is very much more common than general congestion. It may be limited to the trachea and larynx, whilst the bronchi are pale; and in this case it may be confined to one side of the tube. *M. ANDRAL* has seen it cease abruptly at the median line, particularly when one lung was affected; and then the inflamed side of the trachea has corresponded with the diseased lung. The redness may also be confined to the large bronchi, the mucous surface of the passages above and below its seat being pale; or it may be limited to the smaller bronchi, where it often occasions great dyspnoea and fever, with little or no cough. According to *M. BROUSSAIS*, the bronchi of the upper lobes are most frequently congested and inflamed. Congestion and inflammatory injection of the bronchial mucous membrane, although very often connected with diseases of the substance of the lungs, are not necessarily dependent on any of them; for this membrane may be pale from the glottis downwards in cases of acute, and still more in chronic, pneumonia. The same obtains in respect of tubercles, previously to their softening. In many cases, however, where tubercles exist in the lungs, the surfaces of the smaller bronchi are more or less inflamed or congested; and when the tubercles have advanced to softening, the bronchi nearest them are almost always red. Where tubercular excavations exist, the redness is still more marked and extensive, sometimes proceeding along the trachea to the larynx: bronchitis thus supervening to tubercular phthisis. In these and various other diseases, the inflammatory state of the mucous surface commences in the smaller ramifications, and spreads upwards to the glottis. But in other maladies, particularly those which first affect the Schneiderian membrane, throat, fauces, pharynx, &c., the injection of the bronchial surface is chiefly an extension of these; inflammatory action more frequently originating in some one of these situations, and extending itself more or less rapidly, according to the state of the patient, along the surface of the larynx, trachea, and large bronchi successively, until it at last reaches the minute bronchi, or even the air-cells and structure of the lungs. This is the usual direction in which inflammation of the mucous membrane of the air-passages commences and extends itself; but most frequently without reaching the smaller bronchial ramifications, and pulmonary parenchyma.

5. *C. Thickening of the mucous membrane of the air-passages* is a very common lesion, arising, 1st, from its congested or injected state; and, 2d, from its increased nutrition or hypertrophy.—*a.* The former is most frequently observed in the larynx and small bronchi; it is sometimes found in children about the margin of the glottis, giving rise to a form of croup.—*b.* True thickening, or hypertrophy of this membrane, occurs in various

situations, occasioning very different phenomena accordingly, particularly in those who had been affected with chronic coughs. This form of thickening may extend throughout the larynx, or may be limited to the epiglottis, to the entrance of the glottis, to the chordæ vocales, or to the ventricles. In the trachea it may occasion no marked symptom; but in the bronchi, particularly the smaller, it gives rise to sensible alterations of the sound of the pulmonary expansion. It may, when extensive, very materially impede the changes produced by respiration on the blood. Hypertrophy of this membrane may also be confined to a circumscribed point, forming thus a tumour rising above the surrounding surface. This form of thickening may assume a nearly cauliflower appearance, from its exuberance. These excrescences have been found in the larynx by M. ANDRAL and FERRUS.

6. The *mucous follicles* may be enlarged independently of the membrane in which they are seated. When this is the case, a number of round granular bodies, of either a white, red, or dark-brown colour, are found on the internal surface of the membrane, surrounded by two coloured circles — one round the centre, the other round the base. M. ANDRAL thinks that they have often been mistaken for tubercles, and for the variolous eruption.

7. *C. Other alterations of structure in the respiratory mucous membrane.*—*a. Atrophy* is said by ANDRAL sometimes to be observed in this membrane.—*b. Softening* is much more frequent; and is most common in the larynx, especially in the situation of the chordæ vocales and ventricles, where it is sometimes very remarkable, and has been the only change of these parts observed in persons who had either lost their voice or been hoarse long before death.—*c. Ulceration* is not infrequently found in this membrane. Ulcers may be seated in any part of the air-passages, but are more common in the larynx than in the trachea or bronchi. They rarely, however, occur in the larynx, without tubercular ulceration existing also in the substance of the lungs. They occasion various modifications of the voice, according to the parts of the larynx in which they are situated; being found in every point of its internal surface. Their size and number vary exceedingly. Sometimes only one very small ulcer is found, the rest of the larynx being in all other respects quite natural. In other cases, this part is nearly destroyed by numerous ulcers of various shapes and sizes; and in some cases, one large ulcer extends over one half or more of the larynx. Ulcers, when seated in the trachea, are chiefly found in its posterior or membranous part. M. ANDRAL states, that in some cases they are confined to one side of the trachea, which invariably corresponds to the diseased lung; or, if both lungs be diseased, to that which is most affected. Ulcers are not so frequent in the bronchi as in the larynx, but more so than in the trachea.

8. Ulcers in the internal surface of the air-passages sometimes extend no deeper than the cellular tissue connecting the mucous membrane to the subjacent parts. In this case the connecting tissue is much thickened at the bottom of the ulcer. But they frequently proceed deeper, destroying successively the different tissues, until the parietes of the tube are at last perforated, and a fistulous opening is formed between it and some

neighbouring organ or part, as the œsophagus, aorta, parenchyma of the lungs, large blood-vessels, the pleural cavity, &c., or even the external surface; forming, in this last case, a direct communication between its interior and the external air. When a fistulous opening extends into an excavation in the parenchyma of the lungs, it is difficult to determine whether it produced, or was itself occasioned by, the excavation. When it is connected with a cavity arising from the liquefaction of tubercular masses, there can seldom be much difficulty in determining the precedence; but every cavity found in the lungs has not this origin. There can be no doubt that ulcers perforating a bronchial tube may excite inflammation of the substance of the lungs, and occasion either small abscesses, or ulcerations, which enlarge into considerable excavations. But, in the majority of cases, excavations communicating with the bronchi arise from the softening of tubercles; the bronchi being perforated from without inwards, instead of from within outwards, as in the case of ulceration commencing in their mucous surface. The bronchi or trachea may be also perforated from without inwards, by aneurisms, &c. of the aorta, and not infrequently by ulceration commencing in the œsophagus and extending through the membranous part of the trachea; an instance of which I lately had an opportunity of seeing in a patient of my friend, Mr. BYAM. Suppurated bronchial glands may also perforate the bronchi which they surround, and pour their contents into them. A similar result may likewise occur from purulent collections, hydatid formations, &c. of adjoining parts, as of the thyroid gland; instances of which are recorded by PORTAL and ANDRAL.

9. *D. Alterations of the secretions of the air-tubes.*—M. ANDRAL has very justly stated that alterations may occur, 1st, in the gaseous secretion; 2d, in the perspiratory exhalation; and, 3d, in the mucous secretion.—*a. Changes of the gaseous exhalations* are but little understood, and are more matters of inference than of demonstration. There can be no doubt, however, that not only in various diseases, but also in certain states of the system and of the atmosphere, a very material alteration occurs in the proportions of the different gases naturally exhaled by the mucous surface of the lungs. That the successive changes in the system, certain conditions of temperature and of the air, different states of vital energy, and the constitutional differences in the various races of our species, modify very materially the quantity of carbonic acid gas and of azote exhaled from the lungs, may be considered amongst the surest established facts in physiology. (See my *Notes*, &c. p. 626.) Such being the case, it may reasonably be inferred that marked alterations of the gaseous exhalations also take place in disease.

10. *b. The perspiratory exhalations* evidently undergo changes in disease; but their nature and extent are but little known. The vapour exhaled from the respiratory mucous surface very probably may, when excessive, be condensed into a liquid state, and increase the watery fluid sometimes discharged from the lungs. M. ALIBERT states that he has seen, in certain diseases of the skin in which the cutaneous transpiration is suppressed, the pulmonary vapour issuing like steam from the chest, and descending again like an abundant

dew. M. ANDRAL adduces, in his *Clinique Médicale*, the case of a person who suddenly discharged, whilst suffering from hydrothorax, an enormous quantity of a serous fluid from the bronchi, at the same time that the fluid which had been effused in the chest was absorbed.

11. *c.* Alterations of the mucous secretion of the bronchi have been successfully studied by a number of modern pathologists, but more particularly by M. ANDRAL. This secretion is modified both in its quantity and quality. It is often very greatly increased in acute and chronic affections, particularly those immediately affecting the respiratory passages; under which heads the principal changes of this secretion, with the different states and stages of disease, are described. The quantity of the mucous secretion may be so excessive, as to nearly fill up the bronchi, trachea, and larynx, and to suffocate the patient. This sometimes occurs in adults; but, I believe, still more frequently in children, forming in one of its states a species of croup intermediate between true croup and bronchitis; and, in another state, the disease hereafter described as *asthenic bronchitis*. M. BLAUD considers the former, or that seated chiefly in the large bronchi, in which the secretion is consistent and glairy, a "form of croup, and calls it *croup myxagène*." This excessive secretion of mucus is sometimes unattended by any alteration of the air-passages. The mucous secretion may become so viscid as to adhere to the sides of the bronchi; where it may accumulate so as to occasion a fatal dyspnoea, by preventing the passage of the air. In other cases, the mucus is transformed into a puriform fluid; sometimes without any trace of ulceration, or even of redness, in any of the bronchi, the alteration of the secretion being independent of any perceptible change of structure. More commonly, however, patches, streaks, or points of inflammatory injection of the mucous membrane accompany this state of secretion.

12. *d.* Membraniform concretions, or false membranes, form more frequently upon the internal surface of the air-passages than in any other mucous canal. Some pathologists have supposed them to be consequent on the most intense states of inflammatory action in mucous membranes; but this is evidently not the case: they are rather a result of a certain state of the system, probably connected with excess of the albuminous constituent in the blood, together with a disposition in the inflamed vessels to secrete it (see art. *CROUP*). These membranes are generally unorganised, and vary in thickness and consistence in different parts as well as in different cases. According to SCHWILGUE, they consist of albumen, with a small portion of carbonate of soda and sulphate of lime. M. BRETONNEAU has detected fibrine in them. They may exist in patches, or in continuous layers, or in perfect tubes; and extend from the larynx, where they usually commence, to the minute divisions of the bronchi. They rarely originate in this latter situation, and advance upwards; but they often commence in the pharynx, fauces, &c., and extend through the glottis, and down the trachea and bronchi. They are most frequently met with in children from two years of age to puberty; and are not confined to, although most frequent in, acute diseases. In some cases they assume, in children, a chronic character, but only when confined to

the trachea; whilst a chronic state is most common in adults, when they are usually formed in the bronchi. When, however, they occur in the larynx, the tumefaction of the subjacent membrane, the spasms of the muscles, and their own thickness, often give rise to an acute or fatal disease. When seated in many of the small bronchi, they may occasion asphyxy by interrupting the changes produced by the air on the blood. It is probable that *fibrinous* or *polypous* concretions may sometimes form in the bronchi, from the coagulation of a portion of blood exhaled from its mucous surface. LAENNEC has described (*Rev. Méd.* 1824, t. i. p. 384.) a case which appears to be of this description. Such formations differ from the albuminous exudations, in their containing much fibrine, and being of a darker colour than the latter.

13. *e.* Earthy or calcareous concretions occasionally are found in the air-passages, and are sometimes coughed up. They consist chiefly of phosphate of lime; and are formed either in the substance of the lungs, and escape into the bronchi, or in the latter; but more probably in the air-cells. They also have been found impacted in the ventricles of the larynx. The cause of their formation is not well understood. They have been ascribed to chronic irritation of the small bronchi and air-cells; but this source is by no means well established. I have met with them in gouty persons, by whom particularly they are often expectorated during life, recovery generally taking place. *Hydatids* have also been found in the air-tubes. In some cases they may have been developed in this situation; but they much oftener escape into it from contiguous parts.

14. *f.* *Hæmorrhage from the respiratory surfaces* is amongst the most frequent changes to which it is subject. In the greatest number of cases of *hæmoptysis*, the blood is exuded without any ulceration or breach of surface: a slight redness of the mucous membrane being the only change that can be detected. When the hæmorrhage occurs in the smaller bronchi, the blood sometimes accumulates and coagulates in them; imparting a blackish or brownish black appearance to the lobules, and constituting the *pulmonary apoplexy* of LAENNEC. The occurrence of hæmorrhage into the parenchyma of the lungs, is, however, more strictly deserving of this appellation. The extravasation and coagulation of blood in the small bronchi, giving to portions of the lung a blackish and indurated appearance, are most commonly, but not always, found in persons who have expectorated blood, or died from an attack of hæmoptysis; and are most frequent in those cases which supervene in the progress of diseases of the heart. M. ANDRAL considers, however, that the hæmoptysis is not from those sources which have been called apoplectic; but from a larger extent of mucous surface, and from larger tubes. (See art. *LUNGS—Alterations of, and Hæmorrhage from.*)

15. *ii.* ALTERATIONS OF THE OTHER STRUCTURES COMPOSING THE AIR-TUBES.—*A.* The fibrous and muscular tissues of the air-passages experience various changes.—*a.* The fibrous structure of the bronchi is sometimes found either softened or hypertrophied. The thyro-arytenoid ligament is occasionally softened. It has then lost its brilliant colour, become opaque, or even changed into a cellular-like tissue, or an unorganised pulpy substance, leaving the thyro-arytenoid muscle exposed. In this case the voice is remarkably

altered. When the fibrous tissue is hypertrophied, increase of thickness is the chief appearance (ANDRAL).—*b.* The muscular structure, as it exists in the trachea, &c., may be either atrophied or hypertrophied; it may also be softened and destroyed partially or in points by ulceration (§ 7, 8.). But it is chiefly where this structure assumes a different state and function, as in the larynx, that it undergoes marked alterations, giving rise to the most formidable and fatal diseases. The muscles of the larynx are, in some of those cases, softened, more or less atrophied, or even altogether destroyed; and, in others, infiltrated with either purulent or tubercular matter (BOUILLAUD, ANDRAL, and others).—M. ANDRAL states, that he has more than once observed, on examining the larynx of persons who had been long completely without voice, the thyro-arytenoid muscle either remarkably atrophied, or its fibres infiltrated by different morbid secretions; this being the only lesion that could be detected.

16. *B. The cartilaginous structures of the air-passages* are most frequently diseased in the larynx. The cartilage of the epiglottis sometimes loses its natural form: it is scarcely ever ossified; but it is occasionally somewhat indurated, so that it imperfectly protects the opening of the larynx. It is not infrequently destroyed altogether by *ulceration*, commencing either in itself, or in the tissues enveloping it. Similar changes to these sometimes take place in the other cartilages of the larynx. Ulceration of these cartilages may be superficial only; or it may destroy more or less of their structure. It generally commences in the soft parts covering them; but in some cases, particularly of constitutional taint, there is reason to suppose that it originates in inflammation of the cartilages themselves, terminating in the ulcerative process, and the formation of purulent matter in the soft parts adjoining, which escapes by a fistulous opening, generally through the mucous surface into the larynx, and rarely externally. Ulceration may also commence in the articulations of the cartilages; filling them with pus, and destroying their ligaments and articulating surfaces. The thyroid and cryoid cartilages are naturally ossified in old age; and in consequence of disease, in earlier life. M. ANDRAL states, that the arytenoid cartilages have never been ossified. The *rings of the trachea* are sometimes ossified, but seldom or ever otherwise altered. The cartilages of the bronchi are often hypertrophied, becoming more apparent, and forming more complete rings, than natural. They are also sometimes ossified. MM. REYNAUD and ANDRAL found the ultimate ramifications of the bronchi changed into osseous spiculæ, with minute canals (the cavities of the bronchi) running through them, in very old subjects. M. ANDRAL states, that the bronchial cartilages may become so brittle from disease, as to break into fragments, project into the canal of the bronchi, or become altogether detached, and be ultimately expectorated.

17. *C. The cellular tissue* connecting the above structures is often the seat of disease. In the *larynx*, it is very frequently the seat of inflammation and congestion; and, in consequence of a chronic state of inflammatory action, it sometimes becomes indurated and thickened; diminishing remarkably the calibre of the glottis, impeding the action of the muscles, and affecting the form

and movements of the epiglottis. This tissue, in the situation of the larynx and epiglottis, is occasionally infiltrated with *serum*, which, when considerable, constitutes the *œdema of the glottis*, first accurately described by BAYLE. The infiltration may distend the folds of mucous membrane, surrounding the rima of the glottis, so as to obstruct more or less the passage through it. This change is generally consecutive of inflammation of the mucous membrane of the larynx, or of chronic affections of this organ. In some cases it is very chronic; in others very acute, quickly producing asphyxy. Instances of this latter form are to be found in the sixth volume of the *Archives Générales de Médecine*, and twenty-second volume of the *London Medical Repository*. *Purulent matter* is sometimes found in the cellular tissue of the air-vessels, either in the state of small abscesses, or infiltrating it to a greater or less extent; and either in the ventricles of the larynx, or in any other situation in the course of the air-passages. *Tubercular matter* has also been found in various parts of this tissue. Different kinds of *tumours* occasionally compress the nerves supplying the air-vessels, and give rise to symptoms similar to those caused by disease of their parietes. They are sometimes formed in the larynx, or in its immediate vicinity, occasioning more or less complete occlusion of the glottis. M. FERRUS has recorded a case where this result followed the development of two fungous tumours in the larynx (*Archives Génér.* Août, 1824). Several writers have made mention of a *varicose state* of the veins of the air-passages amongst the causes of hæmoptysis; but M. ANDRAL states that he has never met with this appearance in his numerous post mortem inspections.

18. iii. ALTERATIONS OF THE SIZE OR CALIBRE OF THE AIR-VESSELS.—The changes already described very often cause marked change in the air-tubes, either diminishing or increasing their calibre.—*A. Diminution of their canals* are occasioned,—*a.* by the formation of false membranes, chiefly in the larynx and trachea of children, and in the bronchi of adults;—*b.* by thickening of the mucous membrane; occurring principally in the glottis and bronchi;—*c.* by infiltration of fluids into the sub-mucous cellular tissue, chiefly in the larynx and vicinity;—*d.* by various substances formed in some part of these tubes, such as hydatids, coagula of blood, concrete mucus, &c.;—*e.* by compression by some tumour situated externally to some portion of them, as by the thyroid gland, an aneurismal tumour, or enlarged bronchial glands.—*f.* Lastly, there is every reason to conclude, that diminution or constriction of some part of these passages very often arises, although seldom in so permanent a manner as to be observed after death, from spastic contraction of the fibres or muscles belonging to them; particularly when foreign bodies escape into the trachea, or when it, the larynx, and even the bronchi, are irritated by morbid productions—the larynx more especially.

19. *B. Dilatation of the bronchi* was first described by LAENNEC, and afterwards illustrated by ANDRAL and others. It is most frequently observed in the smaller ramifications; and may be so great as to be mistaken for tuberculous excavations.—*a.* In some cases, the bronchi may be uniformly dilated throughout one or more of their

ramifications, some of those which could not naturally receive a fine probe, having attained the size of a goose-quill; and, in some instances, even admitting the finger. These dilated branches are sometimes visible on the surface of the lung, where they terminate abruptly. They occasionally also terminate, particularly near the top of the lung, in an indurated black portion of its substance, or in a cartilaginous mass, or in a calcareous concretion, either exterior or interior to the dilated bronchi.—*b.* In other cases, the dilatation is limited to a particular point of the tube, and has the appearance of an excavated cavity in the substance of the lung, for which it may be mistaken, especially when it is met with in the upper lobe. The size of cavities arising from this species of dilatation varies from that of a hemp-seed to that of an egg. Several of these may co-exist. When they are placed near each other, they form, by their communication, a complicated sinus filled with puriform mucus, and closely resemble some kinds of tuberculous excavations.—*c.* Occasionally they present a third form, consisting of a succession of dilatations, between each of which the bronchus recovers its natural diameter, the walls of the dilated portion being generally thin and transparent. One lung may contain a number of these dilatations.—*d.* The *parietes* of the dilated bronchi are, in some cases, hypertrophied, or more fully developed than in the natural state; in other cases they are reduced to a delicate membrane, presenting neither fibrous nor cartilaginous tissue. (ANDRAL.) The dilated portions generally contain much mucus, or a puriform mucus.

20. These changes of the bronchi are seldom found, unless in persons who had suffered attacks of chronic bronchitis. They are most common in persons of middle or advanced age. But they are also sometimes met with in children who had died of whooping-cough, particularly in its more chronic states, and when complicated with bronchitis. I have occasionally found them in this class of subjects; but only consequent upon this disease. Dilatations of the bronchi, unless when very considerable, seldom occasion any change of the parenchyma of the lungs, beyond compressing and condensing it: they are frequently associated with either grey or dark induration of the adjoining pulmonary substance. (See CHRONIC BRONCHITIS, § 52. 61.)

II. CONGESTION OF THE BRONCHI. — CLASSIF.

1. CLASS, III. ORDER (Author).

21. DEFIN. *Urgent continued dyspnoea; little or no cough, and no expectoration; with an anxious, pale, or livid countenance.* — This affection is not often seen in a primary, severe, and general form; but it is very common in more slight and partial states, and as an attendant on typhoid, malignant, and pestilential diseases, and on exanthematous fevers, especially measles, scarlatina, and small pox, either shortly before the breaking out, or upon the premature disappearance of the eruption, when it often assumes a very general and severe form: and it not infrequently, in slighter grades, ushers in other diseases of the bronchi, particularly hæmorrhage, bronchitis, humoral asthma, &c. General idiopathic congestion of the bronchi, to such an extent and degree as to destroy life, although rare, is sometimes met with. Several cases have been recorded of persons who, without any apparent cause, were seized with

urgent dyspnoea, increasing until it terminated in death; and, on dissection, the only morbid appearance observed was general congestion of blood in the capillary vessels of the mucous and sub-mucous respiratory tissues. (See § 3. for a description of its anatomical characters.)

22. *i.* The *Symptoms* of this affection have not been sufficiently investigated; but they may be stated to consist of continued dyspnoea, more or less urgent; sometimes fever, little or no cough, and no expectoration; the sibilous or sonorous rhonchus in the large tubes, and absence of the respiratory murmur over the chest; diminished resonance on percussion; anxious, pale, bloated, or slightly livid countenance; purplish tint of the lips and nails of the fingers; anhelation, &c. When the congestion takes place in the course of febrile or exanthematous diseases, in addition to these, the pulse becomes very quick, small, irregular, or intermittent, and the oppression at the chest extreme.

23. *ii.* The *Causes* of these congestions are not well known. They appear, however, to be most frequently occasioned by the inhalation of poisonous gases or effluvia; by close, overheated, and crowded apartments; by the ingestion of sedative or narcotic substances, or indigestible or poisonous animal or vegetable matters; by inordinate distension or oppletion of the stomach; and by the transition or metastasis of other diseases, or by their determination to the bronchial surface in a more especial manner, as in the instances above referred to (§ 21.). When this affection proceeds from poisonous or indigestible substances, and not infrequently also when it arises from other causes, it is evidently associated with more or less congestion of the substance of the lungs. It often precedes other pulmonary complaints, as hæmorrhage, and that modification of asthma, called dry catarrh, by LAENNEC. Congestion of the bronchi sometimes also occurs in the progress of several diseases of the heart attended with obstructed or impeded circulation through its cavities, particularly those of its left side; and is often one of those changes which supervene in the advanced stages of several acute diseases, especially the exanthemata, and to which death is more immediately owing (see § 21.).

24. *iii.* The *TREATMENT* must depend upon the state of the vital energies at the time, upon the nature of the causes to which the congestion is owing, and on the evidence of existing general plethora. The state of the pulse in respect of frequency and fulness, will indicate the degree of activity characterising the attack; but generally, when the congestion is considerable, the changes which take place in the lungs during respiration being impeded, the vital energies become proportionately reduced, and the pulse weak, quick, and small. In the majority of cases, it will be necessary, notwithstanding, to abstract blood either by venæsection or cupping; and if the depression of vital power be urgent, to exhibit simultaneously stimulants by the mouth, and in enemata; to employ frictions with irritating liniments (see F. 305. 308. 311.), and revulsants, such as sinapisms, blisters, mustard pediluvia, &c.; and to inhale, at brief intervals, and for a very short time, stimulating vapours, particularly those of ammonia, camphor, aromatic vinegar, &c., with the view of exciting the nerves of the bronchi, and thereby

removing the distension of the capillaries, and accelerating the circulation through them. When, however, the patient, in addition to the symptoms indicating congestion, complains of a sense of heat, trickling, &c. in the course of the trachea, or under the sternum; and if the pulse retains its volume, and still more especially if it be sharp, full, or rebounding; we should infer that the fulness of the bronchial vessels is of an active description, and most probably amounts to determination of blood; and, possibly, constitutes the early stage of hæmorrhage or of inflammation. In cases of this description, full blood-letting, either generally or locally, or both; and afterwards, counter-irritation and revulsion, irritating cathartic injections, the strict avoidance of internal stimuli, and the antiphlogistic regimen; must be prescribed.

25. In every case a strict reference should be had to the cause, associated circumstances, and the complications of the attack, and the treatment should be varied accordingly. When it seems to have been induced, or aggravated, by hurtful substances taken into the stomach, the exhibition of emetics, particularly No. 402. in the Appendix, ought not to be omitted; and, if they fail of operating, the stomach-pump should be used. The bronchial congestion preceding, accompanying, or consequent on the eruptive fevers, is to be combated by cupping, revulsants, rubefacients, stimulating frictions of the surface, and by emetics.

III. HÆMORRHAGE FROM THE BRONCHI.—*Hæmoptysis* (from *ἄμα*, blood, and *πτύσις*, sputum) frequently occurs, and often consists, as already stated (§ 14.), of a simple exhalation from the mucous surface. It is seldom, however, owing merely to the pathological state of the bronchi; but it is either connected with some change in the substance of the lungs, or with impeded circulation through the heart, although the bronchial surface is generally its more immediate source. Being, therefore, intimately related to various changes of the lungs themselves, and often occurring in consequence of these changes, it will be considered in connection with them. (See HÆMORRHAGE FROM THE LUNGS, &c.)

IV. BRONCHII, INFLAMMATION OF THE.—SYN.

Bronchitis, Badham, Hastings. *Erysipelas Pulmonis*, Lommius. *Catarrhus pituitosus, Angina bronchialis*, Stoll. *Catarrhus suffocativus*, Auct. Var. *Bronchitis Catarrhosa*, Hildenbrand. *Peripneumonia Bronchitis*, J. Frank. *Bronchite*, Fr. *Die Entzündung der Luftröhrenäste, Bronchialentzündung*, Ger.

CLASSIF. 3. Class, Diseases of the Sanguineous Function; 2. Order, Inflammations (Good). III. CLASS, I. ORDER (Author, see Preface).

26. DEFIN. *Cough, with or without rigors, often preceded by coryza, and followed by expectoration of a transparent, pale, glairy, and watery fluid; more or less febrile commotion, dyspnœa, and slight soreness, heat, or tightness of the chest, which are diminished as the expectoration becomes more abundant and opaque.*

27. This important disease, until Dr. BADHAM directed particular attention to it, was, according to the particular form it assumed, confounded with common catarrh, with pneumonia, under the appellation of peripneumonia notha, and with other diseases of the lungs and air-passages, more especially tubercular consumption, dyspnœa, &c.

Dr. YOUNG seems to have viewed it as a modification or extension of inflammation of the trachea, or even as synonymous with that disease, probably from their occasional complication, or succession to each other. J. P. FRANK appears to have been among the first who directed attention to the frequency and importance of inflammation of the bronchial surface. "Cum vero," he observes, "profundius per tracheam penetrat, ac in bronchia descendit inflammatio; tunc in primo casu tracheitidis speciem, in altero peripneumoniam imaginem refert, in qua ultima vix non constantem internorum bronchiorum phlogosin in centenis cadaveribus deteximus." (*Interp. Clin.* p. 110.) "Rectam habebis febrium catarrhali saltem fortiozem ideam, si eas pro inflammatione bronchiorum, sive pro bronchitide consideres" (*De Cur. Hom. Morb.* p. i. t. i. c. vi.). BROUSSAIS also noticed the frequency and importance of inflammation of the mucous surface of the bronchi (*Hist. des Phlegmas. Chron.* t. i. p. 75. Paris, 1800.). But it is chiefly to the writings of BADHAM, BROUSSAIS, HASTINGS, LAENNEC, VILLERMÉ, ALCOCK, ANDRAL, and CHOMEL, that we are indebted for our knowledge of it as a specific disease.

28. Bronchitis commences variously, and assumes different forms and states, according to the intensity of the exciting causes, the severity of the attack, and the constitution of the patient. I shall consider it chiefly with reference to its activity and duration, to the states of vital energy, and age of the patient, to its forms and complications, and to its results. Its general prevalence, severity, and not infrequent fatality, require for it a more particular notice than it has received, even recently, from several systematic writers. This will appear somewhat singular, when I state that I know of no disease that is more frequent, or productive of a greater number of deaths, in children, than it, in its different states and complications.

29. i. ACUTE BRONCHITIS assumes different grades of severity, and a modified type, according to the habit of body and vital energy of the patient, and the extent to which the inflammatory action advances along the bronchial tubes. It presents itself in practice, as a *primary disease*, in three forms:—1st, Common catarrhal bronchitis, in which only the mucous membrane of the large bronchi and trachea are affected by the specific and often infectious inflammatory irritation constituting *catarrh*: 2d, Sthenic or true bronchitis, in which the inflammatory action is more acutely marked—is of a more phlogistic description, probably from its further extension along the bronchi, and from both the mucous and the sub-mucous tissue of the tubes being affected: and, 3d, Asthenic bronchitis, where, owing to weak vital energy, the inflammatory irritation assumes a lower and more asthenic grade, and extends still more generally, or affects especially the minute bronchi, interrupting their functions, and preventing those changes from taking place in the blood which are requisite to the support of the nervous and vital manifestations.

30. A. *Catarrhal Bronchitis (B. Catarrhalis)*; *Mild Bronchitis (B. Mitis)*; *Pulmonary Catarrh, Bronchial Catarrh, Catarrhal Fever*; *Bronchitis serosa*, &c.—This is the most common form of the disease, and generally commences with *coryza*,

or with slight hoarseness or sore throat, and other symptoms of catarrh extending down the larynx, along the trachea, to the large bronchi; the affection of the former parts generally subsiding as the latter become diseased. But it sometimes appears without any signs of irritation, either of the Schneiderian membrane, or of the tonsils or fauces, evidently originating in the trachea or large bronchi themselves, particularly in delicate persons, or in those disposed to coughs, pulmonary disease, and habitual expectoration.

31. A sense of roughness, with frequent attempts to clear the throat, is generally the first symptom of the disease. This is accompanied with, or followed by, titillation of the larynx, exciting a dry hard cough; hoarseness of voice, with a sense of tightness across the chest; and sometimes slight pain or soreness upon coughing or breathing deeply. Accompanying these local symptoms, more or less constitutional disturbance is generally present. The patient complains of lassitude, pain in the limbs and back, slight shiverings, or cold chills, quickness of pulse, and increased warmth, with dryness of the skin. The cough, which was at first dry, is now accompanied with a slight expectoration of a somewhat saline, glairy, and thin fluid; and as it rises towards the glottis, increases the cough, and renders the fits more frequent, probably owing to its irritating quality; in this resembling the secretion in coryza, with which it so often originates. In the slighter forms of the disease, the expectoration becomes in two, three, or four days thicker, more abundant and tenacious, less irritating and somewhat more opaque; and with this change, the constriction, pain, and soreness, are diminished, or very much relieved; the pulse also is less frequent, the skin cooler and more moist; the urine less scanty, paler, and deposits a sediment; and the cough less frequent, although often in longer paroxysms. As the amendment advances, the sputum decreases in quantity, but is more opaque, tenacious, and deeper coloured, being frequently greenish white. This amelioration is most remarkable at first in the morning, and, as convalescence proceeds, continues throughout the day. At last but little expectoration takes place, and is observed, as well as the cough, only morning and evening. In slighter cases, the chilliness continues throughout, or alternates, with some increase of heat and perspiration; the pulse is scarcely affected unless towards evening; the expectoration is neither abundant nor very viscid; the fits of cough not severe, and chiefly in the night and morning. Such are the usual symptoms and course of catarrhal bronchitis, constituting what is usually named a cold upon the chest. But it sometimes assumes other characters; and then pulmonary catarrh is no more applicable to it than to inflammation of the substance of the lungs, in which, also, it occasionally terminates.

32. This form of bronchitis appears to consist of catarrhal irritation extending to, or originating in, the mucous membrane of the trachea and large bronchi, to which it is chiefly limited, without materially affecting the sub-mucous tissue. It seems not to be actual inflammation, or, if inflammatory action be present, it is of a peculiar or specific kind, probably owing to its being seated in, or rather limited to, the mucous membrane; in which light it is viewed by HILDEN-

BRAND, who very justly considers catarrhal irritation to be distinct from true inflammation. This variety may assume an epidemic form, when its symptoms become somewhat modified (see INFLUENZA); and repeated or prolonged attacks of it often favour the development of tubercles in the lungs, or even originate them, in scrofulous and delicate subjects. It may also pass more or less rapidly into either true acute bronchitis, or into the chronic form of the disease, owing to the extension of inflammatory action more generally through the bronchi, and to their sub-mucous cellular tissue.

33. *B. True Bronchitis (B. Vera); Sthenic Bronchitis (B. Grovis Sthenica); the Acute Mucous Catarrh of LAENNEC.* — This more decidedly inflammatory form of the disease is sometimes preceded by coryza or sore throat; and as these begin to yield, the morbid action extends along the mucous membrane to the trachea and bronchi. But it frequently also commences in this last situation, particularly in those who are liable to pulmonary disease, and to chronic coughs, and assumes a severe form. After these preliminary signs, sometimes hoarseness, or loss of voice, and always a dry hard cough, with a sense of soreness, rawness, dryness, and heat, are complained of under the sternum, preceded by marked chills or complete rigors. The chills at first alternate with increased heat and dryness of the skin; and are soon followed by quickened and somewhat laborious respiration; dyspnoea or oppression at the chest; sometimes a dull pain on coughing; quick, full, and often strong pulse; sickness or loss of appetite; pain in the forehead, back, and limbs; loss of animal strength, with an inability to leave the couch or bed; foul loaded tongue; constipated bowels, and scanty high-coloured urine. As the disease advances, the frequency of pulse, the cough, expectoration, and general febrile symptoms, increase, as well as the tightness and soreness of chest; the latter sensation often amounting to an obtuse pain extending between the shoulders to the back, and to the attachments of the diaphragm to the false ribs, sometimes with pale anxious countenance, and great oppression and anxiety. As expectoration comes on and increases, the sense of heat below the sternum diminishes. The cough is generally excited by a full inspiration; and from being short and dry, or attended by but little expectoration, becomes longer, more severe, and convulsive, accompanied with a more copious expectoration; and subsequently, in some cases, terminates in scanty vomiting, which promotes the discharge of a watery or serous and frothy mucus, sometimes in considerable quantity, which had accumulated in the bronchi and trachea. The febrile and other symptoms are aggravated towards night, which is generally sleepless and disturbed, the position of the body being on the back; but the posture is often changed. In some cases, particularly those which are not remarkably severe, each exacerbation of the fever is attended by chills; and throughout the disease, the sensibility of the surface to cold is very great. In the more phlogistic cases, especially in plethoric subjects, the dyspnoea and oppression are very urgent, the face is flushed, and sometimes slightly tumid, and the eyes injected. At a still more advanced period,

the tongue is often red at its sides and point, and deeply loaded in the middle and base; the breathing becomes rattling or wheezing, owing to the air struggling through the mucous accumulation in the bronchi, and the exertions to expectorate greater. In extreme cases of this description, collapse, with diminished expectoration, purple lips, orthopnoea, quick depressed pulse, cold perspirations and extremities, with threatening suffocation, occur as early as the sixth or eighth day.

34. The chief characteristic of this true form of bronchitis is the state of the *sputum*, which ought always to be carefully examined. When the disease attacks a person who never expectorates whilst in health, the cough remains dry for a considerable time; and those who expectorate habitually, cease to do so when the inflammatory attack is very acute. If the disease be slight, the sputum is often increased from the commencement, and its quality changed. As long as the cough continues dry, the disease may be said to be in its first stage. In the course of a period which varies with the constitution of the patient and the treatment employed, each fit of coughing is followed by the excretion of a clear, transparent, serous or watery mucus, which is at first slightly saline, but afterwards becomes tasteless. It is without odour. As the disease advances, it is a glairy mucus, resembling white of egg. When it is poured into one vessel from another, it flows with extreme viscosity. The more it can be drawn out into a fine thread, and the greater its tenacity, the more marked is the irritation of the surface secreting it; the greater also being the oppression, heat, and anxiety in the chest, the violence of the cough, and the general febrile symptoms. In these very acute cases, it adheres closely to the sides of the vessel containing it by long striae. When the fits of coughing are severe, there is a froth or sort of lather on its surface; and, in some cases, it is streaked with a little red blood, which, however, is not combined with the mucus as in pneumonia. Early in the disease, whilst the expectoration is fluid, transparent, or watery, it often contains small whitish flocculi, proceeding from the mucous cryptæ of the pharynx and fauces.

35. In proportion as the inflammation advances to *resolution*, the sputum loses its transparency, and is mixed with opaque, yellowish, whitish, or greenish matter, which increases until it forms nearly the whole of the expectorated mass, and is attended by a marked diminution of the symptoms: its quantity also is lessened. The inspection of the sputa thus not only serves to indicate the nature of the disease, but also its various stages. In cases of a relapse or aggravation of the inflammatory action, the sputum again becomes transparent, frothy, more abundant, and viscid; and the other symptoms increase. In several instances the disease will continue to fluctuate for several days, exhibiting symptoms of slight amelioration, soon followed by relapse or exacerbations, often occurring on alternate days, or at the certain period, and assuming from this circumstance a remittent character, until either a more decided improvement takes place, or a more marked aggravation, terminating in some one of the ways hereafter to be detailed (§ 39.).

36. In the two forms of the disease now de-

scribed, the minute bronchi so far escape, during the favourable course of the disease, as that no material interruption to the functions of the lungs, in respect of the changes effected on the blood during respiration, takes place in them; the air still passing through them and reaching the air-cells: but, in certain of their very severe forms and complications, and of their unfavourable terminations, and in the variety next to be noticed, obstruction to the free circulation of air, and to the changes produced on the blood, in the lungs, occurs to a greater or less extent.

37. *C. Asthenic Bronchitis (B. Asthenica)*; *Peripneumonia Notha** of Authors; *Acute Suffocative Catarrh* of LAENNEC.—This variety of the disease generally occurs in very young, or in aged persons, in those of a phlegmatic or cachectic habit, and of lax fibres and exhausted powers of constitution, or who have been liable to chronic coughs, and to copious expectoration of a thin watery phlegm. Severe paroxysms of cough, with wheezing, and oppressed breathing; foul loaded tongue; scanty urine; complete loss of appetite; very quick, small, or irregular pulse; little or no increase of heat, excepting at night; cold extremities; vertigo; pain in the head; exacerbating fits of dyspnoea, with a scanty expectoration at the commencement, gradually becoming abundant and frothy; are its chief symptoms in persons advanced in life. It is much less acute or phlogistic in its character than the preceding variety; and its duration is longer. In the more severe cases, the countenance is pallid and anxious; the oppression of the præcordia extremely great; and a full breath taken to relieve it brings on a severe fit of coughing, which sometimes terminates in vomiting, and relieves for a time the symptoms by favouring the excretion of the accumulated mucosities. The tongue is often dry, and brownish red at its point and edges, and sometimes covered at its base with a dark coating; the breathing is much more difficult; the lips and nails assume a blue livid appearance; the face becomes lurid or dusky; the patient cannot lie down in bed, or, if he does, starts up, after falling asleep, with a sense of suffocation; and the symptoms indicate either collapse, and obstruction of the air-passages, or effusion of fluid in the thoracic cavities, or even both: stupor or sopor; weak, wiry, and very frequent pulse; marked diminution of the sputa, cold extremities, orthopnoea, clammy sweats about the face and neck, suppressed urine, &c., ushering in a fatal termination.

38. This is, upon the whole, the most common form of bronchitis which is met with in *children*, particularly in the metropolis, and among the children of the poor, ill fed, and ill clothed, and those living in cellars, ground floors, and badly ventilated lanes and apartments, and is often remarkably prevalent during the winter and spring. In this class of patients its approach is often insidious; and it usually commences with coryza, but not infrequently also with chills, febrile symptoms towards evening, wheezing, quick breathing,

* "*Peripneumonia notha* fortior nobis bronchiorum catarrhus est, quo in pituitosis, obesibus, senibus, cachecticis, laxisque hominibus frigida et humida sub tempestate, ab accedente membrana mucosa: hos canales inventientibus irritatione, copiosior, tenaxque pituita celeriori passu secreta bronchiorum fines opplendo, suffocationem sat cito minatur." (J. P. FRANK.)

and cough. There is at first little or no dyspnoea; but the tongue is loaded, the pulse accelerated and full, the face pallid or tumid, and the child has lost its animation. As the disease advances, the breathing becomes more quick and laborious; and fits of dyspnoea come on, generally followed by severe attacks of cough, which often terminate in vomiting; on which occasion only the bronchial secretion is presented for examination, and is found to consist at first of a viscid, watery mucus, and afterwards of a yellowish white, or a tenacious matter. These exacerbations are followed by remissions, during which the child dozes, and appears relieved, and the pulse becomes less frequent. Thus the disease may continue, with alternate remissions and exacerbations, for many days, until either a permanent diminution of the symptoms takes place, or an increased frequency of pulse, stupor, lividity of the lips and nails of the fingers, convulsions, &c. supervene, and indicate impending suffocation, with congestion or watery effusion on the brain.

39. **TERMINATIONS.** — *A. Duration.* — The *sthenic* variety of the disease usually runs its course in about seven or nine days; but it may terminate either way as early as the fifth; or it may be prolonged to the 21st, or even the 28th day. Its duration will, however, chiefly depend upon the treatment employed, the complication it may present, the severity of the symptoms, and on the age and constitution of the patient. The *asthenic* form of bronchitis generally runs its course in a slower manner; it seldom terminates either way in less than fourteen days, and generally continues for several weeks (§ 37.).

40. *B.* In *favourable* cases, the *sthenic* form of the disease begins to decline from the fifth to the ninth day. The change is first evinced by the state of the sputum, as above described (§ 35.); by an amelioration of the cough, dyspnoea, and febrile symptoms: in rare instances, by copious epistaxis; by a more general and copious perspiration than that which frequently terminated the febrile exacerbations; by a more copious discharge of a paler urine, depositing a sediment; and by a diminution of the dyspnoea, of the frequency and severity of the cough, and of the quantity of the expectoration, which becomes pearly, opaque, thick, yellowish, or greenish yellow; at last febrile symptoms occur only towards evening, and the disease disappears as in the first variety (§ 31.).

41. *C.* This favourable change is not, however, always observed, particularly when the attack is very severe, when treatment has either not been soon employed, or has not been sufficient to remove the disease, or when the secretion into the bronchi has been very profuse, and expectorated with much difficulty. In such cases, it either lapses into the chronic state about to be described; or, owing to the extension of the inflammation to the air-cells and substance of the lungs, gives origin to pneumonitis, and even to pneumonitis combined with pleuritis, which is thus superadded to the original disease; or, from the great extent of surface affected, the consequent irritative fever, and interruption to the pulmonary functions, and the profuse viscid fluid filling up the bronchi, collapse of the powers of life supervenes, and the patient dies, either with cerebral affection, or with the usual symptoms of asphyxy, consequent

upon diminished discharge of the morbid secretion, and its accumulation in the air-tubes.

42. *a.* When the disease thus terminates in *pneumonia*, the sputum becomes more rounded, thick, tenacious, and streaked with blood, which is more or less intimately mixed with it, and sometimes of a dark colour, giving it a rusty appearance; and the cough is more tight, hard, and deep. The oppression also increases; the cheeks are flushed with circumscribed red; the pain of the chest is more severe, or is now complained of for the first time; the skin is partially covered with moisture, sometimes very abundant in parts; the chest, which was hitherto sonorous throughout, is dull, in some part or other upon percussion; and the auscultatory signs of severe and dangerous pneumonia appear, on which delirium and other unfavourable symptoms often supervene, and terminate, with coma, the life of the patient.

43. *b.* Bronchitis, as it occurs either in the *sthenic* or *asthenic* form, may also terminate in chronic pleuritis, and in effusion of serum into the pleural cavity, and in some instances also into the pericardium, particularly in persons advanced in life, and in those who have experienced difficulty in the circulation through the cavities of the heart. In some instances of this description, the expectoration, and many of the other symptoms, are suddenly or quickly diminished; but the dyspnoea continues, and signs of effusion become more apparent as those of bronchitis disappear. In these, the consecutive effusion occurs in the form of a translation or metastasis of the morbid action from the mucous to the serous surface. In other cases, symptoms of pneumonitis, or pleuritis, intervene between the change in the bronchitic symptoms and the occurrence of effusion, with pain, more or less severe, loss of resonance in some part of the chest, and other auscultatory signs, indicating the extension of the inflammatory action first to the small bronchi, and thence to the substance of the lungs and the pleura. Dr. HASTINGS has detailed some cases of this termination in his work, and I have treated several instances at the Children's Infirmary; but it is chiefly the aged who are liable to this unfavourable occurrence.

44. *c.* In other unfavourable cases, the disease becomes, in the course of a few days, characterised by failure of the energies of life; oppression and uneasiness increase; the cough is more frequent, laborious, and convulsive; the sputum is either more abundant, frothy, tenacious, and glairy, or gelatinous, and excreted with great difficulty, or much diminished in quantity from want of power to excrete it; the pulse is more rapid, small, weak, and irregular, or intermittent; the pain of the head more distressing, the countenance is pale, and the face and neck covered with a clammy sweat; the respiration very frequent and wheezing, sometimes with an audible rattle; and, at last, delirium, lividity, at first of the lips, afterwards of the countenance, great prostration of strength, and coma, supervene, and the patient sinks with all the signs of imperfectly changed blood. In some cases, cerebral symptoms come on much earlier, with either violent or low muttering delirium, which soon terminates in most profound coma. In a few cases, this early accession of delirium, or of violent headach, with other symptoms of consecutive inflammatory action,

ending in serous effusion on the brain, altogether removes the original bronchial inflammation, or in others moderates it greatly and masks it. I have observed this in *children*, and once or twice in robust adult persons; but in both classes of subjects it is a dangerous occurrence. More commonly, however, the cerebral symptoms continue increasing, with those referrible to the bronchi, till life is extinguished.

45. In other cases of very acute bronchitis, with very high fever and severe local symptoms, particularly with quick, laborious, short respiration, dyspnoea, anxiety, great sense of heat under the sternum, and bloated countenance, collapse takes place rapidly, particularly if an appropriate treatment have not been early employed; and either delirium, coma, and other cerebral symptoms, or those more directly depending on the circulation of venous blood, appear, and the patient is speedily cut off. In weak and nervous patients, and during unfavourable states of the air, the inflammatory action sometimes seems to invade nearly all the respiratory mucous surface, and is soon productive of a copious mucous secretion, which, either from its difficult excretion or rapid secretion, in some cases, speedily suffocates the patient.

46. In *children*, and rarely in adults, cases occur, in which the inflammatory action extends upwards, to the *trachea* and *larynx*, occasioning all the symptoms of laryngitis in addition to those of bronchitis, and frequently terminating fatally with convulsions and the signs of congestion in the head. In many of the unfavourable cases of bronchitis in children, the extent of the disease, and the copious secretion, occasion suffocation more or less rapidly, with somnolency, bloated, or livid countenance, convulsions, coma, and, at last, complete asphyxy: and, on dissection, congestion of blood, with watery effusion, is found within the cranium; the bronchi are filled with a muco-purulent matter, and the vessels of the lungs are loaded with blood.

47. COMPLICATIONS.—The most common states of complication, in which bronchitis presents itself in practice, are, 1st, With catarrhal sore throat, coryza, &c. of which it is generally consecutive, and with catarrhal inflammation of the pharynx and œsophagus. 2d, With inflammation of the trachea, or larynx, or both, of which it is most frequently consecutive; but also sometimes antecedent, as I have occasionally observed in children. Indeed, we have seldom croup in London uncomplicated with bronchitis in some one of its forms or states. 3d, With measles, scarlatina, or small pox, on which it very frequently supervenes; particularly in measles, sometimes very early in the disease, and before the eruption breaks out; but oftener in consequence of its premature disappearance, or retrocession. 4th, Very commonly with whooping-cough, especially during certain seasons and epidemics. 5th, Not infrequently with continued fevers, particularly in its asthenic form. 6th, Often with disorders, or even sub-acute inflammation, of the digestive mucous surface, and diarrhoea, in children, when it also assumes this form; the stools being offensive, and the tongue red at its point, &c.* 7th, With dis-

ease of the liver, and accumulations of bile in the gall-bladder, chiefly in adults; the tongue then being very deeply loaded with a yellowish brown crust, or fur; and the stools dark coloured, and most offensive. 8th, In some cases with erysipelas, particularly its epidemic and infectious form. 9th, With pneumonia, or pleuritis; these being either consecutive of the bronchitis, or simultaneous with it. 10th, With dropsical effusion into the pleura or pericardium, especially in aged persons; and, 11th, With inflammatory irritation, in the substance of the brain, or in its membranes, with disposition to effusion, — a complication most commonly met with in children.

48. All these diseases are greatly aggravated, and their danger increased, from being associated with bronchitis; and they frequently terminate fatally by one or other of the unfavourable states which the bronchial affection assumes. Bronchitis thus complicated, also presents, in consequence, either a more acute character, or the asthenic form; and, being attended by a more marked disposition to invade the smaller ramifications and air-cells, or by a more profuse secretion of mucus, and a rapid depression of the powers of life, the unfavourable terminations above described quickly supervene. In several of these complications, particularly with pertussis, measles, scarlatina, continued fever, cerebral affections, and diseases of the lungs or pleura, bronchitis often escapes detection, until it becomes either one of the most important, or the most dangerous, or an actually fatal lesion. When thus complicated with measles or other exanthematous diseases, the eruption, if it still continue on the surface, often assumes, as the powers of life sink, a dark or purplish hue; and a slight dirty blueness of the skin, particularly of the face, hands, &c. is generally observed in other cases, indicating the impeded functions of respiration, and the consequent changes in the blood. The frequency and importance of the complication of bronchitis with measles, especially before the appearance of the eruption, during its progress, and after its decline; and the occurrence of the former complaint, both during and after convalescence from the latter; are deserving of the careful attention of the practitioner.

49. ii. SUB-ACUTE BRONCHITIS is characterised by the symptoms of the sthenic form of the disease in a milder and more chronic form. The cough continues longer dry, and the expectoration scanty, or thick, viscid, gelatinous, or albuminous, with tightness of chest, and oppressed breathing. In this form of the disease, a plastic albuminous exudation sometimes forms in the large bronchi, and lower part of the trachea, or in the large bronchi of only one lung, and is moulded in the form of the air tubes; and is either expectorated in fragments, or in large tubular branches and ramifications. Cases of this description are detailed under the appellation of bronchial polypi by the older writers, and figures given of them by TULPIUS and others. Mr. LEEF has published (*Lond. Med. Repos.* vol. xviii. p. 207.) a case of this description, wherein this production retained its ramified and tubular form. I have met with two cases where the albuminous exudation had been formed in the bronchi, and

* During some seasons I have occasionally admitted in one day, at the Infirmary for Children, several cases, in which it was difficult to determine whether the digestive

or the respiratory mucous surface was most affected. This complication is not infrequent during convalescence from the exanthemata, particularly measles and scarlet fever.

expectorated in fragments. It generally occurs in an uncomplicated state.

50. iii. CHRONIC BRONCHITIS often follows severe attacks of catarrh; and is also frequently consecutive of acute bronchitis; but it sometimes occurs primarily in the chronic state, particularly in aged persons. It differs in nothing from the acute or sub-acute forms, excepting in as far as the symptoms are altogether milder, and their continuance longer; there being no distinct line of demarcation between its grades of activity and chronicity. The chief means, by which we are enabled to infer, that the disease has assumed a chronic form, when it is consequent on the acute, is the continuance of the sputum for several days, in undiminished quantity, and the persistence of the opaque, whitish yellow, or yellowish green appearance, which it assumed upon passing from the transparent, fluid, and viscid condition characterising the acute form.

51. Chronic bronchitis assumes various grades of severity, and presents different phenomena, according to the changes which have taken place in the bronchi. In its *slighter states*, and primary form, as it is often met with in persons advanced in life, and as it prevails during winter and spring, or variable seasons, it consists chiefly of a frequent and almost habitual cough, with scarcely any pain in the chest, continuing for weeks, or even months, or recurring every autumn, winter, and spring; being most severe in the mornings, and much easier through the day, with slight dyspnoea on exertion, and copious viscid mucous expectoration; but without any marked febrile symptoms, excepting slight acceleration of pulse. Its *severer forms* are met with in young or middle aged persons, after catarrh or acute bronchitis; and are attended with fits of coughing, and copious expectoration; with oppression at the chest and præcordia; with febrile symptoms, particularly towards night; with copious perspirations in the morning, which often seem to increase the cough instead of relieving it; with loss of strength, emaciation, and slight disorder of the digestive organs. The cough is increased after getting into bed, and very early in the morning. The breathing is quick and laborious, particularly on any exertion; and the patient complains of slight tightness of the chest. The pulse generally ranges from 90 to 120; being the former whilst quiet in bed, and the latter towards evening.

52. Attention to the *expectoration* is very important, in order to enable us to judge both of the accession of this state of the disease, or of its aggravation or change into the acute form, which is not infrequent, and of the concurrent or consecutive alterations which often take place. The sputum occasionally continues long in the state now described. It is generally then inodorous, and without taste. But it oftener becomes greenish, or yellowish white, or muco-purulent; is mixed with a colourless watery phlegm, and is more or less abundant. In cases of a worse character, particularly when hectic symptoms are present, it assumes a more purulent appearance; is sometimes streaked with blood, or mixed with dark specks of blood, or consists chiefly of pus. These changes, however, seldom occur without much antecedent fever, and attendant emaciation, night sweats, occasional diarrhoea, and the symptoms of confirmed hectic. In rarer cases, the sputum

becomes remarkably foetid; but this change cannot be imputed to any particular lesion of the bronchi or lungs, excepting sometimes to considerable dilatation of the former. The whole of the symptoms in this class of cases so very nearly resemble tubercular consumption, as to be distinguished from it with much difficulty, and only by attending to the appearances of the sputum, and by examining the chest with the stethoscope.

53. The *sputum* generally partially swims on the surface of water. When it is thin, transparent, viscid, and frothy, it usually altogether swims; but when it is thick, in tenacious, opaque lumps, or in fragments resembling portions of albuminous exudation, it generally sinks. In all these states it cannot be diffused in the water. When it consists of yellowish white, or greenish yellow matter, it partly sinks, and by agitation is broken into ragged portions, and is partially diffused; and the more it approaches a purulent state, the more completely and readily is it diffused, imparting to the water, by agitation, a yellowish white appearance.

54. Chronic bronchitis is also sometimes *consecutive* of the eruptive diseases; but these diseases have generally altogether or very nearly subsided before the bronchial affection supervened. It occurs primarily from the irritation of minute particles of mineral or vegetable substances floating in the air, as is shown in the article on AIRS. It is sometimes also *complicated* with other chronic diseases of the lungs and pleura, more especially with *tubercles*; with diseases of the liver; with chronic inflammation, or other disorders of the mucous surface of the digestive tube, particularly of the œsophagus, stomach, and large bowels. In all these consecutive and complicated states, it presents no certain or unvarying forms; its chief character, its duration, progress, and termination, being modified by its severity, by the constitutional powers of the patient, by his diathesis, and by the quantity of expectoration. In some cases, the secretion from the bronchial surface is so profuse as to be the chief cause of the exhaustion and death of the patient.

55. iv. ANATOMICAL CHARACTERS OF BRONCHITIS.—A. When the body of a patient is opened, that has sunk under any disease whilst affected at the same time with a *mild and recent bronchitis*, some redness is found, generally in a circumscribed portion of the mucous membrane, and usually towards the end of the trachea, and in the first divisions of the bronchi. If the inflammation have been more *intense*, the redness extends to a greater number of these tubes, and exists, moreover, in the smaller ramifications. It sometimes happens that this redness is exactly limited to the bronchi of one lobe only; and it is the bronchi of the superior lobe which seems to be more particularly disposed to inflammation. The red colour of the bronchi presents itself occasionally under the form of a fine injection, which seems to exist both in the sub-mucous cellular tissue, and in the mucous membrane itself, and is usually attended by slight tumefaction. Sometimes the vessels cannot be distinguished, but only a number of small, crowded, red points, which are agglomerated the one around the other. Finally, an uniform red colour is occasionally observed. In some cases, the redness diminishes progressively from the large bronchi to the

small ones; in others, an opposite disposition is remarked. Occasionally the redness only exists in intervals, in the form of bands or of isolated spots, forming, as it were, as many circumscribed phlegmasiæ, between which the mucous coat is white and healthy.

56. *B.* When the inflammation is *chronic*, the mucous membrane generally loses its lively redness: it presents a livid, violet-coloured, or brownish tint. Finally, and what is very remarkable, in individuals offering all the symptoms of inveterate chronic bronchitis, with puriform expectoration, the mucous membrane of the lungs has been found scarcely rose-coloured, and even perfectly pale through its whole extent. BAYLE and ANDRAL have particularly noticed this fact. I would not wish to conclude that there is not, and least of all, that there has not been, inflammation in these cases; but I think a very copious secretion will often take place from mucous surfaces, and assume even a purulent appearance during its retention in the bronchi, from lost tone of the extreme capillary vessels, with, perhaps, an increased flux or determination of the circulating fluid in order to supply the discharge, all vascularity disappearing with the cessation of circulation. The other changes observed on post mortem inspection, particularly in the more chronic states of bronchitis, consist chiefly of thickening, softening, ulceration, &c. of the mucous membrane, dilatation of the bronchi, &c. (See § 7, *et seq.*)

57. *v.* DIAGNOSIS.—The characters of the *cough*, and of the *sputa*, and the physical signs, are our chief guides in the diagnosis of bronchitis. The history I have given of the disease will be generally sufficient to enable even the inexperienced to recognise it: but it will often be necessary to arrive at more precise and certain information as to the extent of lesion, and its existence either in a simple or in a complicated form.

58. *A. Of the acute.*—*a.* *By auscultation.*—In the first stage of the disease, the inflammation causes tumefaction of the mucous bronchial surface, and consequent diminution of the calibre of the tubes. This state occasions a modification of the respiratory sound in them: and, hence, either with the unaided ear, or with the stethoscope, we hear at first the “*dry bronchial rhonchus*,” consisting chiefly of a sibilous or whistling sound; occasionally with a deeper tone, resembling the note of a violoncello, or the cooing of a pigeon, particularly when the large bronchi are affected. These sounds (see AUSCULTATION, § 14.), denominated the *sibilous* and *sonorous rhonchi*, are present chiefly in the early stage, and before expectoration takes place; and proves the accuracy of the rational inference of Dr. BADHAM, that the difficult breathing of this period is owing to the state of the mucous membrane; and I would add, of its sub-mucous cellular tissue also. To these sounds is added the *mucous rhonchus*; and in proportion as the bronchial secretion, to which it is owing, augments, this sound becomes predominant. When the inflammation is seated in the large tubes, the bubbles of mucous rhonchus are large and uneven; and the respiration may be still heard over the chest. But when the mucous rhonchus is fine, and is heard constantly, it may be inferred that the small bronchi are invaded. When this is the case in a severe degree, there is

also slightly diminished resonance of the chiefly affected part upon percussion. As the disease proceeds, and the secretion passes into an opaque and thickened state, the mucous rhonchus becomes interrupted, sometimes with obstruction of the respiratory sound in a portion of the lungs, and passes into a sibilant or clicking sound. These changes arise from the entire or partial obstruction of one or more tubes by the thickened mucus, and are generally of temporary continuance: occurring now in one part of the chest, and disappearing; and now in another. This state of the bronchi fully explains the dyspnoea of this stage.

59. *b. Rational diagnosis.*—*a.* The *cough* in *bronchitis* is loose, diffused, and deep; in *paroxysms*, and attended with fever, often with wheezing. In *pertussis*, it is in severe paroxysms, unattended by fever or wheezing; is accompanied with a distinct whoop; and terminates in vomiting. In *croup* it is sonorous, clanging, and harsh. In *laryngitis*, it is suffocating, shrill, or grunting; and, on inspiration, attended with a drawing down of the pomum Adami to the sternum, and retraction of the epigastrium and hypochondria. In *pneumonia*, it is deep in the chest; frequent and short, often hard; and gives a metallic sort of noise. And, in *pleuritis*, it is short, dry, hard; sometimes slight, but always suppressed and painful.—*β.* The *expectoration* in *bronchitis* is abundant after the second or third day, or even from the first: in *pertussis*, it only follows the vomiting: in *pneumonia*, it is more rounded, distinct, thickened, purulent, rusty, and intimately streaked with blood: in *pleuritis*, *croup*, and *laryngitis*, it is scanty, thin, frothy in the latter; sometimes with shreds or pieces of lymph, and entirely different in appearance from that of bronchitis.—*γ.* *Pain* in *bronchitis* is scarcely complained of; and consists merely of a sense of soreness, heat, and tightness in the chest, particularly beneath the sternum, and is not increased on full inspiration: in *pneumonia*, it is more marked, especially in certain parts of the chest, generally nearer the lateral regions, and is increased on inspiration or prolonged expiration: in *pleuritis*, it is very acute, and a full inspiration is impossible: in *croup* and *laryngitis*, the pain is increased upon pressing the trachea and larynx.—*δ.* The *countenance* in *bronchitis* is more frequently pallid or bloated; in *pneumonia*, it is generally flushed; and dyspnoea is greater in the former than in the latter. The breathing is *wheezing* and *hurried* in acute bronchitis; in *pneumonia* it is less so, and generally without the bronchial wheeze. The *pulse*, in the former, is frequent, full, free, developed, and soft; in the latter, full, hard, bounding or vibrating, and sometimes oppressed and undeveloped. The general febrile symptoms are more continued in *pneumonia* than in *bronchitis*; morning remissions, with free perspiration, being more frequent in the latter than in the former. The *physical signs* in *pneumonia*, *pleuritis*, &c., are the surest means of their diagnosis. (See art. LUNGS—*Inflammation of.*)

60. Some cases of *asthenic bronchitis* may be mistaken for *humoral asthma*; and occasionally no very distinct line of demarcation can be drawn, both affections either insensibly passing into each other, or being complicated with one another. But, generally, the slow accession of the former,

the more continued and less urgent dyspnoea and tightness of the chest, and the presence of febrile symptoms, particularly great quickness of pulse, will distinguish it from humoral asthma; which is commonly characterised by the sudden accession of the paroxysms, their severity during the night, and the attendant orthopnoea, the more or less complete and prolonged intermissions, and especially by the absence of fever, and by the much more marked integrity of the vital and animal powers than in asthenic bronchitis. In this latter disease, the patient is incapable of leaving his bed or his apartment: in asthma, he may attend to his avocations; or may, at least, change his room in the intervals between the fits. The diagnosis between the *sthenic* bronchitis and asthma is attended with no difficulty. (See *ASTHMA*, § 50.)

61. *B. Of the chronic.*—*a. By auscultation.*—The physical signs of this form of bronchitis are not materially different from the acute. The respiration is extremely varied: being sometimes louder, at other times more obscure than natural, and generally accompanied with the *mucoous rhonchus*; which, however, is not heard over the chest, but now chiefly in one part and then in another, and seldom during the whole of the respiratory act. The occasional occurrence of the *sibilous* and *sonorous* rhonchi indicates that the tubes are sometimes partially obstructed; but this is much less frequent than at the commencement of acute bronchitis; and it rarely happens that the respiration is entirely interrupted in a part of the lung. Very often, also, when the dyspnoea is considerable, or even urgent, the air is heard to enter the lungs as well as usual, the respiratory sound being either distinct or puerile. The resonance of the chest on percussion is scarcely diminished. When the bronchitis is very chronic, the tubes sometimes become *dilated*, from being weakened by the inflammation and stained by the paroxysms of coughing. When this state of the bronchi exists, the sputum is often foetid, and several of the auscultatory signs of tuberculous excavations of the substance of the lungs are present. If the dilations be large and rounded, it may furnish *pectoriloquy* and the *cavernous rhonchus*; but if, as is more generally the case, it extend to several tubes, or if they be dilated along a considerable portion of their axis, a loud *bronchophony* is only heard. If this dilatation be extensive, bronchophony, bronchial respiration, sometimes with a "*veiled blowing*," and even slight pectoriloquy, will be heard in corresponding parts of the thorax. On *percussion*, the sound is often somewhat less than natural, owing to the compression of the surrounding pulmonary tissue; and owing, also, to this cause, the dyspnoea is often great. Dilated bronchi remain long stationary; tuberculous excavations generally increase rapidly. The former are most frequently situated in the scapular, mammary, and lateral regions; the latter in the sub-clavian and sub-acromian regions of the chest. (See the *diagnosis of TUBERCULAR CONSUMPTION*.)

62. *b. Rational diagnosis.*—It is chiefly with tubercles in the lungs that chronic bronchitis is liable to be confounded; and, indeed, without the aid of auscultation, the diagnosis between them is very difficult. When they both co-exist, and especially when the latter is attended with dilat-

ation, we have seen that even auscultation does not easily enable us to ascertain the exact state of disease: however, by a careful comparison of the physical and rational symptoms of both, we may generally form a tolerably correct opinion. Early in chronic bronchitis, the absence of pain during inspiration, the capability of resting on either side, the pallidity of the lips and countenance, and the appearance of the sputum (§§ 34, 35.), and the wheezing noise on respiration, may readily distinguish it from tubercular phthisis. As the disease advances, the symptoms more nearly resemble tubercular consumption; but the pallor of countenance and absence of pain generally continue; or, if the latter be present, it is diffused over the chest, and the patient can draw a larger volume of air into the chest, and retain it longer, than in phthisis. The dyspnoea is less on exertion, consists more of a stuffing sensation, and is more relieved by expectoration; the sputum generally consists of a more considerable portion of mucus, and is more regularly abundant; and the perspirations are much more partial, the emaciation less, and the paroxysms of hectic much less regular, than in tubercular disease. The cough is very different. In chronic bronchitis, it is generally deep and sonorous, and in paroxysms; in phthisis, it is short and tickling. When we find copious purulent expectoration, but without broken-down portions of softened tubercles or of the pulmonary tissue; night sweats; hectic fever, with full deep cough, and absence of the physical signs of phthisis;—if, after repeated examinations, there can be detected neither a constant absence of the respiratory murmur, nor gurgling cavernous rhonchus, nor pectoriloquy, nor marked defect of resonance on percussion,—we may safely conclude the disease to be chronic bronchitis. When this disease depends upon the inhalation of irritating substances, as Dr. HASTINGS very justly remarks, the cough and copious muco-purulent expectoration often continues for months, or even years, without much suffering, with pale countenance, slight lividity of the lips, &c. In these cases there can be no difficulty in the diagnosis.

63. *vi. Prognosis.*—*A. In the acute.*—When the disease is slight, or limited to a few bronchi only, the disease generally terminates favourably. The change is indicated by a more perfect *apexia* in the mornings, less severe and less frequent cough, easier expectoration, and a thicker and more opaque sputum; which, however, generally assumes a more fluid and glairy appearance for a few evenings during the febrile exacerbations. A *relapse* of the disease is indicated by increase of the fever and cough, and a more transparent, fluid, and glairy expectoration. When the inflammation is very severe and general, as indicated by high fever, dyspnoea, &c., the prognosis should be unfavourable, or given with caution. If symptoms of collapse have appeared, and the mucoous rhonchus be heard universally, and with little or no respiratory murmur upon auscultation; if the pulse becomes very frequent, small or weak, irregular or intermittent; and if the countenance be at the same time pallid and anxious, slightly livid, or the nails of the fingers and lips tending to purple; the danger from asphyxia is extreme. When the disease occurs in the course of continued or exanthematous fevers, in some epidemic states of hooping-cough, and in the other severe

forms of complication (§§ 47, 48.); and when the signs indicating the unfavourable terminations already enumerated appear, the danger is also great, although it may not be extreme. The supervention of pneumonia or pleuritis, or of tracheitis or laryngitis; a sudden diminution of the expectoration; the occurrence of cerebral symptoms, of orthopnoea, or even continued dyspnoea, with expansion of the nostrils; a dark red colour of the tongue; are all unfavourable circumstances, and indicate imminent danger. On the other hand, when spontaneous evacuations occur, with a favourable change in the cough and expectoration, particularly on one of the critical days, although the attack has been extremely severe, a favourable result may be looked for, more particularly if the disease proceeded from cold, and was uncomplicated.

64. The *asthenic* form of the disease is very dangerous, when occurring at the extremes of age; but less so when it is unattended by marked depression of the powers of life, and by signs of the circulation of venous blood, — circumstances which, in connection with the frequency, weakness, and irregularity of the pulse, the quantity and appearance of the sputa, and with the difficulty of expectoration, constitute the danger.

65. *B. In the sub-acute and chronic.* — If it have arisen from catarrhal affection, and be unattended by much emaciation or hectic, this form of the disease will generally terminate favourably, although the expectoration present a puriform appearance. The more purulent, however, this excretion, and the more marked the symptoms of hectic, the greater the danger. But when the sputum seems to consist chiefly of mucus, although the quantity expectorated be great, a favourable issue may take place; and this will be more frequently the case when the chronic bronchitis has been consecutive of the acute. When there are constant dyspnoea, very frequent pulse, profuse sweats, and copious purulent expectoration, with emaciation, hectic fever, colliquative diarrhoea, associated symptoms of disease of the liver, or of the mucous surface of the bowels, with a smooth, glossy, or chopped, a dark red, or raw appearance of the tongue, a most unfavourable prognosis should be given; and if to these succeed aphthous eruptions about the mouth and tongue or fauces, little hope of recovery can be entertained. The causes and complications of the disease should also materially influence our prognosis. When it has arisen from mechanical irritation of the bronchi, patients often recover from a very unfavourable state, when the irritating cause has altogether been removed. The occurrence of bronchitis in the scrofulous diathesis, and its association with tubercles in the lungs, are dangerous circumstances. This complication is to be ascertained chiefly by means of the physical signs. If these indicate the existence of tubercles, or do not establish with certainty their absence, a very cautious opinion should be given. The mucous rhonchus, and dulness on percussion, with the rational symptoms of tubercles, are indications of a very dangerous malady. The rapid development of symptoms of the acute, in the course of chronic bronchitis, must be viewed as an unfavourable circumstance. The extremes of age also increase the risk in this as well as in the acute state of the disease.

VOL. I.

66. *VI. CAUSES.* — *A.* The *predisposing causes* are — whatever lowers the energies of the frame, more particularly too warm or crowded apartments; sleeping with too many clothes; late rising, late hours, and too great sexual indulgence; very early, and far advanced age; the lymphatic and sanguineous temperaments; relaxed habits of body; febrile and exanthematous diseases, and the suppression of accustomed eruptions and discharges.

67. *B.* The *exciting causes* are, exposure to a cold and moist atmosphere, or to currents of air, particularly when perspiring; rapid vicissitudes of weather and season; wearing damp clothes or shoes; or sleeping in damp beds or linen; continued exposure to dry cold; quick refrigeration of the body after being over heated and fatigued, or upon coming from crowded apartments and assemblies; wearing too low or very thin dress, with exposure of the neck and chest; rapid atmospheric changes, particularly during autumn, winter, and spring, and especially from cold to heat; epidemic constitutions of the atmosphere; easterly and north-east winds; exposure to the night air after rain; the inhalation of irritating gases, vapours, or mineral or vegetable particles (see ARTS AND EMPLOYMENTS, as Causes of Disease, § 40.); sudden passage from the cold air into overheated apartments; catarrhal infection; miasmatic exhalations in cold and moist states of the air; the imperfect irruption or retrocession of the exanthematous diseases; and the translation or metastasis of gout, rheumatism, erysipelas, &c.

68. *viii. TREATMENT.* — *Ist, OF ACUTE BRONCHITIS.* — *A.* *In its simple states.* — M. BROUSSAIS gives a very concise view of the indications of cure in this form of the disease, which has been adopted, *verbatim*, by Dr. HASTINGS; without, however, referring to the original writer. M. BROUSSAIS very justly recommends that the excitement of the sanguiferous system should be moderated, by general blood-letting, acidulated and mucilaginous fluids, and abstinence from stimulating food; that perspiration be favoured, by saline and antimonial medicines, and by emollients, both internally and externally employed; and that the irritation and congestion of the diseased vessels be relieved by local depletions and emollient revulsants when erythema of the capillaries predominates, and by rubefacients and vesicatories when the nervous powers are depressed.

69. *a.* *In the first variety of the disease, blood-letting is seldom requisite; saline and antimonial medicines, with demulcents, emollients, &c. being generally sufficient. When, however, fever is considerable, and the patient complains of soreness or slight pain in the chest, a moderate bleeding—preferably by cupping—will be serviceable; and the solution of the potassio-tartrate of antimony, in frequently repeated doses, will soon remove all febrile disturbance. The following mixture has generally answered this purpose in my practice. (See also F. 393. 854.)*

No. 66. R. Mist. Camphoræ, Mist. Amygdal. Dule. aa ʒ ij; Liq. Ammoniac Acet. ʒ jss.; Spirit. Æther. Nit. Vini Antimon. Potass.-Tart., aa ʒ ijss.; Syrupi Tolutani ʒ jss. M. Capiat coch. ij. larga, secundâ quâque horâ.

70. *In the third variety, or the asthenic form of the malady, blood-letting is generally required; but it ought to be resorted to with much caution, and early in the disease, as recommended by SYDENHAM and most practical writers of the present*

day. From eight to ten ounces may be taken from a vein, but, I think, preferably from between the shoulders by cupping; and afterwards, revulsants, counter-irritants, and expectorants, may be employed. The admissibility of depletion, or of antimonials, or the extent to which they should be carried, and the propriety of having recourse to stimulating expectorants, necessarily depend, in this form of the disease, upon the degree of morbid action and of vital power presented by individual cases, and upon the quantity of the expectoration and the difficulty to excrete it. Moderate local depletions are more generally required when this state of disease occurs in children, than when it is met with in aged persons; whilst the latter are more benefited by expectorants, diaphoretics, counter-irritants, and diuretics, than the former class of subjects.

71. In the *second variety* of bronchitis, particularly when the patient is young, plethoric, or robust, blood-letting should be early employed, and directed as recommended in the art. on the Blood (§ 64.); and a full impression made upon the circulation, short, however, of syncope. Immediately afterwards, the preparations of antimony, combined according to circumstances, should be given in frequently repeated doses, so as to prevent the return of excessive local or general action, and to promote a free and universal perspiration. The preparations of antimony that may be selected for this purpose are the ant. potass.-tart., James's powder, or the kermes mineral (F. 637.): and the first doses of them may be advantageously combined with calomel. The following may be exhibited; or F. 24. 513. 530. 638., or other similar formulæ, contained in the Appendix:—

No. 67. R. Hydrag. Chloridi gr. vj.; Pulv. Antimonii Comp. gr. v.; Camphoræ rasæ gr. j.; Extr. Hyoscyami gr. v.; Conservæ Fosar. q. s. ut fiat Bolus statim post venæsectionem sumendus.

No. 68. R. Mist. Camphoræ ʒj.; Liq. Ammon. Aect. ʒij.; Potassæ Nitratiss gr. vj.—x.; Spirit. Æther. Nit. ℥xx.; Vini Antimon. Potass.-Tart. (vel Vini Ipecacuanhæ) ℥xx.—xxx.; Tinct. Hyoscyami ℥xv.; Syrupi Tulutani ʒj. M. Fiat Haustus, tertius horis capiendus.

When antimonials are given in sufficient doses, and frequently repeated after the first depletion, a second will not often be necessary; or local blood-letting will be sufficient. But if the febrile excitement and the state of the pulse and of the blood drawn indicate it, venæsection may, in robust subjects, be again repeated to the extent already indicated. When this variety of the disease affects *children*, blood-letting, either general or local, according to the age, should be prescribed, with saline diaphoretics, followed by the semicupium or pediluvia. In all classes of subjects, *blood-letting* must be regulated according to the state of the pulse, heat of skin, the character and quantity of the expectoration, the presence of pain, and the prevailing character of diseases; attention to these circumstances being especially required in children and aged persons.

72. *b.* The choice of *diaphoretics* in this disease is deserving of notice. Early in the *first* and *second* varieties I have usually preferred the potassio-tartrate of antimony, generally in solution, and conjoined with the vin. ipecacuanhæ, or with the spirit. ather. nit., small doses of camphor, &c. But in infants or very young children, in the aged, and in the *third* or asthenic form of the disease, ipe-

cauanha seems preferable,—in the latter class of subjects particularly, combined with camphor. In the more catarrhal, or less acute, forms of the complaint, ipecacuanha, combined with nitrate of potash and opium, and, in the more sthenic states of the disease, the same medicines, in larger doses, will often prove equally serviceable as the preceding. While febrile excitement continues much increased, diaphoretics or diuretics are often exhibited with little advantage, as the restoration of the cutaneous and urinary secretions is rather the consequence, than the cause, of diminished or exhausted febrile commotion. The object, therefore, should be, first to lessen the excitement by depletion, alvine evacuations, and sedatives; and then to employ those diaphoretics which produce a lowering and refrigerant effect, until the strength of pulse and heat of skin are reduced. Hence the propriety of adopting the medicines already recommended, and combining them with the nitrate of potash, and with each other.

73. *c.* *Emetics* are amongst the most beneficial remedies we can resort to in certain states of bronchitis, particularly in the *third* variety; and, in the *second*, after blood-letting; in children they are often remarkably useful. They have the effect of unloading the bronchi of the mucus accumulated in them, of relaxing the surface, and afterwards of promoting perspiration. For children, ipecacuanha should be preferred; and for aged persons, and the third variety of the disease, the sulphate of zinc. In the second form, and in all other subjects, the potassio-tartrate of antimony is the best emetic that can be prescribed, as it operates by vomiting, by lowering the vascular action, and promoting perspiration. Emetics are more particularly required when the expectoration is difficult or suppressed, the cough severe and suffocating, and when the disorder depends upon the inhalation of irritating particles. They moreover tend to promote the operation of purgatives, which are generally much required in this disease. In cases of extreme depression, with suppressed excretion of the secretion, the stimulating emetics in the Appendix (F. 402, 403.) should be selected.

74. *d.* *Purgatives* and *cathartics* have been considered by several writers as of doubtful efficacy in pulmonary inflammations; and, when expectoration is established, as being even prejudicial. Such appears also to be partly the opinion of an able reviewer in the *Medico-Chirurgical Review* for Dec. 1820. But it is not quite in accordance with my experience, which, at the Infirmary for Children alone, must have amounted to some thousand cases of the different forms of the disease. It should be kept in recollection, that the expectoration in bronchitis is not a salutary discharge from the lungs, the promotion of which is a beneficial indication of cure; but that it is the product of a morbid state, of the nature of which it is an index; and that this state is generally inflammatory, and always attended with determination of the circulating fluids, thereby keeping up the discharge. It is obvious, that whatever tends to increase the morbid determination to the bronchial surface will increase the disease, and, consequently, the expectoration; and that whatever derives from this situation will proportionately diminish both. That purgatives or cathartics, judiciously combined, have the effect of deriving from the lungs, by increasing the se-

cretions of the liver and digestive mucous surface, must be evident; and I have accordingly found them serviceable when thus prescribed. Severe attacks of bronchitis, moreover, are favoured by congestions and accumulations of bile in the biliary organs, and by sordes retained on the mucous surface of the bowels. In all those cases more especially—wherin the stools are generally very offensive—and at the commencement of all the forms of the disease, these medicines ought to be exhibited, with the view not only of promoting the abdominal secretions, and of removing fecal matters and sordes, but also of deriving the circulation from the seat of disease; and the bowels should be kept very freely open throughout the treatment. It is, of course, understood that we are not to prescribe cathartics to the extent of depressing the energies of the frame too low, especially when they are already weak. Indeed, purgatives may be as much required, and as beneficially employed, in asthenic cases, as in others of a more phlogistic description, particularly if the bowels have been neglected; effects of a very different nature from that of mere evacuation arising from a judicious choice and combination of them. Thus, when prescribed with bitters, tonics, stimulants, or antispasmodics (F. 266. 471. 572. 880, 881. 887.), in the asthenic or suffocative states of the disease, not only will full alvine evacuations be procured, but also a tonic effect on the digestive organs; and, consecutively, a more moderate secretion in the bronchi, with an easier expectoration, will be produced. I have observed that the combination of purgatives, especially calomel, or those of the resinous class, with camphor, antimony, and hyoseyamus, according to the circumstances of the case, is particularly serviceable in bronchial diseases.

75. *e.* *Expectorants* have been much abused in inflammations of the bronchi; chiefly from the circumstance of the expectoration being too generally viewed as a salutary discharge which ought to be promoted, instead of its being a product of the inflammatory state, or of active determination to the surface of the air-vessels. I consider them quite inadmissible when there is much fever, or heat of skin, or when the sputum is abundant and fluid, the patient having sufficient strength to bring it up; and generally in the *second* variety of the disease. On the other hand, in the *third* variety, or when the expectoration is arrested evidently from want of power to throw it off, or to excrete it, or from its great viscosity, expectorants will be of much service. In such cases, *ammonia* and *camphor* should be first tried, as being generally least detrimental in doubtful cases, and most quickly beneficial. Where the admissibility of expectorants is evident, especially in the asthenic form of the disease, and in aged persons, *squills*, *ammoniacum*, *galbanum*, or *senega*, may be directed; with the precautions, and in the forms, recommended when treating of them with reference to humoral asthma (see *ASTHMA*, §§ 89. 103.; and R. No. 41—46.). When expectoration is rendered difficult, and the cough suffocative, from the tenacity and consistence of the sputum, as is sometimes the case, *attenuants* and *alteratives*, as the fixed alkalies combined with ipecacuanha, &c., or as prescribed in the article on *ASTHMA* (§ 103. R. No. 50, 51.), and exhibited with camphor or ammonia, will be found of much service. In

nearly all states of bronchitis, *camphor* is a most valuable medicine. Its virtues have been singularly overlooked by the writers on this disease; but, when combined with *colchicum*, or with antimony, nitrate of potash, ipecacuanha, &c., and given in small doses, in the more inflammatory and febrile states of the disease; or when prescribed in progressively larger quantities, with *diuretics*, the spirit, aether, nit., opium, &c., as the vascular excitement subsides, and febrile heat disappears; and in large doses (from five to ten grains), with ammonia, ammoniacum, senega, opium, &c., when exhaustion and difficulty of expectoration from deficient power are urgent; it is one of the most valuable remedies we possess in this, as well as in several other diseases.

76. *f.* The *inhalation of emollient and medicated vapours* are occasionally of much benefit in the sthenic form of the disease, but chiefly in its first and second stages. The vapour arising from a decoction of marsh mallows, or from lined tea, or from simple warm water, is the best suited to this state; and should be employed from time to time, the *temperature of the apartment* being duly regulated through the treatment, and constantly preserved from about 66° of Fahr. to 75°. Dr. PARIS recommends, during the dry easterly winds of spring (when the disease is so prevalent), the vapour of warm water to be diffused in the patient's apartment. In the early stage it may be of advantage. In the case of the son of an eminent medical writer, attended by Dr. GORDON, Mr. ANNESLEY, and myself, this was tried in the state of the air alluded to, but with no benefit. The case terminated fatally, from extension of the disease to the air-cells and substance of the lungs. When the expectoration becomes whitish, opaque, and thick, the vapour may be rendered somewhat more resolvent by adding a solution of camphor in vinegar, and extract of conium or hyoseyamus to the hot water, or to the emollient infusions now mentioned; and in the asthenic variety, particularly when the difficulty of expectoration, and the fits of dyspnoea, are distressing, or when the excretion of the morbid matter is impeded or suppressed from want of power, the medicated vapours and gases recommended in the chronic state of the disease (§ 98.), and in humoral *ASTHMA* (§ 88.), may be tried.

77. *g.* There are various medicines which are occasionally useful, when exhibited in appropriate states and periods of the disease. Amongst these, *narcotics* and *sedatives* deserve an especial notice. *Opium* should not be exhibited alone, as long as febrile action is great; but, in combination with antimony, or ipecacuanha, and nitre, it is often a most valuable medicine. It is best given in small or moderate doses, in conjunction with camphor and expectorants, where vital power is reduced and expectoration difficult (§ 37.). In general, when the skin becomes cool, the bowels are well evacuated, and the air-tubes remain irritable, opium, or some other narcotic or anodyne, is indispensable. Opium, and others of this class of medicines, particularly when judiciously prescribed, are then of service, not only in diminishing the irritability of the system and of the air-passages, and in lessening the cough, the frequency or severity of which often aggravates the inflammatory irritation of, and determination to, the bronchial surface, but also in equalising the circulation, in determining to

the skin, and promoting perspiration. In the more phlogistic states of the disease, and at its commencement, *colchicum* or *digitalis* will be often of advantage, in diminishing vascular action, local determination, and morbid irritability. They ought, however, seldom to be used at the same time. In the more sthenic cases, *digitalis* is very beneficially associated with the preparations of antimony. When the sputum is thick and opaque, *colchicum* is generally less beneficial than at an earlier period, excepting in conjunction with diuretics and camphor. When the skin has become cool, it is no longer of use. In the *third* variety, it is seldom indicated, unless at the commencement of the disease, or when combined with ammonia and camphor. Upon the whole, both *colchicum* and *digitalis* are less to be depended upon in acute bronchitis, than a judicious combination of antimonials with anodynes, &c. *Hyoscyamus*, *coniium*, and the extracts of *poppy* and of *lettuce*, are also very generally serviceable in the different forms of bronchitis. But with them, likewise, the amount of advantage will entirely depend upon the manner in which they are prescribed. In the sthenic and febrile states of the disease, and at its commencement, they should be associated with antimonials, ipecacuanha, refrigerants, demulcents, and emollients (F. 24. 208. 427. 554.); with diaphoretics (F. 394. 563. 809.); and with diuretics (F. 818. 865. 893.); or in other similar forms, of which there are several in the Appendix. When the disorder assumes an asthenic state, or when expectoration is difficult, the cough distressing, and the skin cool, any of the sedatives particularised may be conjoined with either ammonia, camphor, or the fixed alkalies, or with other attenuants (F. 835.), and with expectorants, &c. (F. 356. 555. 558. 811. 895.) according to circumstances.

78. *h.* When the acute form of the complaint seems to be about lapsing into the chronic, the combination of *gentle tonics* with emollients and diaphoretics is often of service, as was first pointed out by M. BROUSSAIS, who allowed also red wines, much diluted with water, in this state. The infusion or decoction of cinchona, or the infusion of *uva ursi*, may be thus prescribed:—

No. 69. R. Decocti vel Infusi Cinchonæ ʒ iijss. : Liq. Ammon. Acet. ʒ jss. ; Mucilag. Acaciæ ʒ ss. ; Spirit. Æther. Nit. ʒ iijss. ; Tinct. Camphoræ Comp. ʒ ss. ; Extr. Conii gr. xx. ; Syrupi Tolstanti ʒ ss. M. Capiat Cochlearæ unum amplum secundâ vel tertiâ quâque horâ, vel Coch. ij quintis vel sextis horis.

79. *i.* *External measures* ought not to be overlooked during the course of the disease. In respect of *local* or *general depletions*, nothing need be added to what has been already stated. The former of these should always be preferred when doubts are entertained as to the propriety of taking any considerable quantity of blood; and, in the sthenic form of the disease, may be resorted to at an advanced stage, particularly when the change in the expectoration, and other symptoms (§ 35.), indicate a return or exacerbation of the inflammatory action. *Blisters* are not admissible in the early stages of sthenic bronchitis. But, in the asthenic disease, or when inflammatory action and febrile heat have been subdued by repletions, &c., blisters are of much service, and may be applied either between the shoulders or on the breast; and, in some severe cases, re-applied or kept discharging for some time. In young children, and in adult or aged persons, when the secretion of

the bronchial surface is profuse, and the powers of life much exhausted, I have derived more permanent advantage from the use of the rubefacient *liniments* in the Appendix (F. 295. 296. 311.), rubbed assiduously twice a day over the chest or back, than from blisters. When blisters are employed, much benefit will sometimes arise from removing them as soon as slight redness of the skin is produced, and covering the part with a large warm bread and water poultice, which ought to be frequently renewed; or by applying a succession of warm fomentations. In some extreme cases of this description, I have seen much advantage derived from applying over the epigastrium and lower part of the chest, a flannel wrung out of hot water, and immediately afterwards soaked with the spir. terebinth., and allowing it to remain until severe burning heat of the skin is produced by it. If suffocation be threatened either by the profuseness of the secretion, by its difficult expectoration, or by exhaustion of the vital energy; and if we be, as we then unfortunately are, at a loss for any probable means of success; this will sometimes have a remarkable effect, and save the life of the patient, particularly when assisted by the internal use of camphor, ammonia, &c. At the time of my writing this, a case occurred, attended by Mr. Faxon and myself, where immediate relief and a speedy recovery followed this almost *dernier resort*. And I have often witnessed a similar result, in other most dangerous cases of this description, from the internal as well as the external use of this most valuable remedy, particularly at the Infirmary for Children, where I have for many years had recourse to it in cases of danger.

80. The *tepid bath*, or *semicupium*, will often be of service early in the disease; and in its course sponging the surface of the chest, or of the whole trunk, with warm water and vinegar, and afterwards with the warm nitro-muriatic acid lotion (F. 834.), particularly towards the decline of the disease, when we dread its lapsing into the chronic, and in the asthenic variety, will often prove of essential service. The common *beverage* of the patient during the treatment should be regulated according to the state of febrile action, and its compatibility with the treatment directed. Barley water, with any of the vegetable acids, tamarind water, or any of the formulæ or drinks (*vide Potus*), contained in the Appendix, may be directed.

81. *B. Of the complicated states.*—*a.* Bronchitis is not infrequently associated, particularly at its commencement, with *sore throat*; inflammation existing not only in the *fauces*, but extending to the *pharynx*, and through the larynx down the trachea and bronchi. This state of disorder sometimes obtains in *scarlet fever*, forming a complication of remarkable danger. I have also observed it, in a very severe form, affect six members of one family, and three of another, both living in the vicinity of the metropolis, in a low damp situation, all of whom had long previously had scarlatina. In some of these cases the danger was great, and all were severe and of the asthenic type. Purgatives, first consisting of calomel and James's powder, and subsequently combined with stimulants and tonics, were actively exhibited. Demulcent linctuses (*see Linctus*, in the Appendix), or astringent, cooling, and antiseptic gargles; external revulsants, and rubefacients; the inter-

nal exhibition of camphor, combined with antimonials, hyoscyamus, diuretics, and afterwards with ammonia, mild attenuants, expectorants, and tonics; the liquor ammoniæ acetatis, with infus. cinchonæ, spirit. æther. nit., or spirit. ammon. arom., &c., formed also the chief means of cure. All the cases terminated favourably.

82. *b.* When the disease is complicated with scarlet fever, the treatment will altogether depend upon the character of the prevailing epidemic, and the circumstances of the case. Early in the complication, local depletions are sometimes required; and afterwards, full doses of camphor or ammonia, or of both, — particularly if the eruption prematurely disappear, or present a dark tint, or if the auginous affection assume an ash-colour, or a dark red or brownish hue, — are amongst the chief remedies to be depended on. I have met with severe cases in which the bronchial disease either preceded, or followed, the efflorescence and decline of the eruption in scarlet fever; and in the course of this association most violent cerebral symptoms have supervened; thus forming a double complication. These cases, although extremely dangerous, are not necessarily fatal. Local depletion, sometimes to a very considerable extent, may be practised, chiefly by leeches applied over the sternum, behind the ears, or below the occiput, or by cupping on the nape of the neck; and calomel, antimony, revulsants, purgatives, camphor, ammonia, &c., according to the circumstances of the case, should be prescribed. Counter-irritation by rubefacient liniments is particularly required in complications of the disease with scarlatina or measles. Formulæ No. 299. and 300. may be used for this purpose, or the following: —

No. 70. R Camphoræ ʒj.; Pulv. Capsici ʒss.; Olei Mæis ℥xxx.; Olei Olivæ ʒjss.; Liq. Ammon. ʒvj. Misce. Fiat Linimentum.

83. *c.* The appearance of the disease with measles, either previous to, in the course of, or subsequently to, the eruption; or even its accession during convalescence, is a very frequent occurrence. This association was very common in the winter and spring seasons of 1829, 1830, 1831, and 1832; during which epoch, blood-letting was not so generally indicated, nor so well borne, as in former years, the bronchial affection being more frequently of the asthenic type. In general, however, local depletions are required early in the disease, and, in some cases, may be carried to a considerable extent; often much further than in its association with scarlatina. I have sometimes found it necessary to deplete locally in both these states of complication, at the very time when I judged it proper to exhibit camphor or ammonia in considerable doses. But in many instances, particularly during the years above specified, patients have recovered as readily when no sanguineous depletion has been employed, as where it has. Bronchitis occurring either in the course of scarlatina, measles, or small pox, requires active counter-irritation and revulsion; and the means recommended for this purpose (§ 79.) to be decidedly enforced. The observations I have already made respecting the use of inhalation (§ 76.) also apply to such cases. When these exanthemata commence with bronchial symptoms, emetics are then of decided advantage. And, if they be accompanied with sore throat,

purgatives ought to be given in decided doses, the bowels freely acted upon throughout, and enemata occasionally thrown up, particularly F. 140. 149. 794.

84. *d.* When bronchitis occurs in the course of continued fevers, the same general principles of treatment are required, as have been specified in respect of scarlatina and measles. In all these states of complication, this disease should be viewed as a marked manifestation, in a particular organ, of the morbid state prevailing more or less throughout the frame; and it should be kept in recollection, that this affection always, in some measure, impedes the changes effected by respiration on the blood, thereby increasing the morbid condition of this fluid existing more or less in all severe cases of exanthematous fevers, and at least the disposition to it that obtains even in simple continued fever. The extent to which depletion should be carried in this complication, or the propriety of employing it at all must depend upon the character of the fever, of the prevailing epidemics, and the particular symptoms and circumstances of the case. I have seen a strong, and regular-living man, with fever thus complicated, very dangerously depressed by a single small depletion. Purgatives are, however, better borne, particularly when combined with camphor or ammonia; and occasional large doses of calomel combined with camphor, and followed in a few hours by a cathartic draught, will be found of much service in promoting the functions of the liver, and enabling it to remove those elements from the blood, which so readily accumulate in it to a hurtful extent, when their elimination by the lungs is impeded. Much advantage will also arise from the use of blisters applied for a few hours, and often repeated; from the use of the rubefacient liniments above specified; and from the inhalation of the vapour of warm water, with a solution of camphor in vinegar added to it.

85. *d.* The association of the sthenic form of bronchitis with tracheitis and laryngitis, either affection preceding the other, requires full depletion, general or local, or both; large and repeated doses of calomel, with antimony; the tepid or warm bath, or semicupium; internal and external revulsion, by cathartics, purgative enemata, &c.; emetics, particularly when the paroxysms of suffocation and stridulous respiration are urgent; the inhalation of watery, emollient, and anodyne vapours; and a free use of diluents, emollients, &c., with the carbonate of soda, the sulphuret of potassium, small doses of the sulphuret of ammonia, or of the sulphuret of copper, in extreme cases, until nausea or vomiting is occasioned, &c. Blisters are seldom of much service in this state of disease, particularly whilst the symptoms of croup are present. They ought never to be applied over the throat, as occasionally directed, and, in some cases, not without mischief; although recovery has taken place in others, notwithstanding the risk they occasioned of increasing the local irritation.

86. *e.* One of the most frequent complications presented to us in practice is that of bronchitis with hooping cough. In some cases, this complication commences with the usual symptoms of catarrh, on which those of bronchitis supervene; the characteristic signs of hooping cough, particularly the convulsive fits of coughing, with the

inspiratory whoop, and vomitings, not appearing for some days subsequently. In other cases—and those, perhaps the most numerous—the inflammatory affection has not appeared until after the invasion of pertussis. When thus associated, bronchitis may be either sthenic or asthenic; the one or the other being more generally prevalent in some seasons than in others. During the years specified above (§ 83.), the asthenic state was most common; and I have seen several cases in which sanguineous depletion had been injudiciously practised, particularly as respects quantity. Cerebral symptoms are apt to occur during this complication, and also infiltration or hepatisation of a part of the substance of the lungs. These unfavourable terminations should be anticipated and prevented by small local depletions,—by leeches applied behind the ears; by the exhibition of camphor combined with ipecacuanha, or antimonials, and narcotics, particularly conium or hyoseyamus; by diaphoretics with diuretics; and more especially by the use of the liniments and revulsants already recommended (§ 79.). (See HOOPING COUGH.)

87. *f.* The simultaneous occurrence of inflammatory action in both the *digestive* and respiratory mucous surfaces is not infrequent, particularly in children; and means calculated to benefit the one, generally aggravate the other, or risk the accession of cerebral disease. I have found small local depletions, followed by the pulv. ipecacuanhæ comp., combined with small doses of calomel, or hydrarg. cum creta and camphor; the warm bath and frictions, with the stimulating liniments already specified (§ 79.); the application of blisters for a few hours only, and often repeated; the liq. ammoniæ acet., with spirit. æther. nit., camphor mixture, diuretics, &c., constitute the principal means of cure.

88. *g.* The association of *hepatic disorder* with bronchitis is not rare. But the affection of the biliary organs does not always precede the bronchial disease: it often occurs in its progress; an increased, as well as a morbid, secretion of bile supervening, probably in consequence of the vicarious increase of function of the liver, and its irritation by, and elimination of, the morbid elements accumulated in the blood, owing to the impeded function of the lungs. This complication requires the use of mercurial purges combined with camphor and antimony, particularly James's or kermes powder (F. 637.); external irritants and revulsants, cathartic enemata (F. 151.), &c. A similar treatment is indicated when the disease is connected with the translation of erysipelas, gout, or rheumatism.

89. *h.* If the inflammation extend to the *substance of the lungs* or *pleura*, the antiphlogistic treatment should be rigorously enforced: the solution of the potassio-tartrate of antimony ought to be given in frequent doses, and carried as far as circumstances will permit; internal and external revulsants resorted to at the same time; and diaphoretics and diuretics suited to individual cases prescribed. In some instances, either *colchicum* or *digitalis*, or both, may be substituted for the antimony; but they answer better, particularly the *digitalis*, after this medicine has previously been used. If we have reason to suppose that *effusion of serum* has taken place in the thoracic cavities, diuretics, and, amongst others, *digitalis*, should be employed; re-

collecting, however, that the accumulative and sinking effects of either *digitalis* or *colchicum* sometimes appear very rapidly, and in an alarming degree, when they are given either at the same time or after the exhibition of the potassio-tartrate of antimony. Disease of the brain or its membranes supervening in the course of bronchitis has been considered in the article BRAIN (§ 186.).

90. The *SUB-ACUTE FORM* of bronchitis requires in all respects the same treatment as the acute uncomplicated disease, but not carried so far; the activity of the means should have due relation to the acuteness of the attack, and the effects they produce.

91. 2d. OF CHRONIC BRONCHITIS.—M. BROUSSAIS has very justly stated the indications of cure in chronic bronchitis to be, 1st, to diminish the general excitability, and to keep the circulation quiet; 2d, to solicit the excitement and the fluids to other organs, particularly towards the skin; and, to these I would add a 3d, namely, to restore the healthy tone and functions of the bronchial surface, by means which seem to have this effect either directly or indirectly. It is obvious, however, that the accomplishment of the first and second intentions have an indirect influence in bringing about the third.

92. *a.* General *blood-letting* is inadmissible in this state of the disease; and even local bleedings should in many cases be employed with caution. Cupping, however, to a moderate extent, is very frequently required; and it is evidently more advantageous to repeat the operation to a small extent, than to abstract a large quantity at once. When the disease has existed long, and is attended with a copious discharge, much general debility, and absence of pain upon full inspiration, even local depletion cannot be ventured on. Next in importance to depletion is *counter-irritation*; and for this purpose several means are presented to us. When there is a tendency to acute action, or when the cough is at all painful, and the sputum puriform, either the tartarised antimonial ointment, or a large issue or seton in the side, is preferable: but when there is very marked relaxation of the bronchial mucous surfaces, blisters, and rubefacients, or a succession of them, seem more appropriate. I have, however, found in a number of cases, the *liniments*, No. 296, 297, 311. in the Appendix, productive of much greater advantage, and more generally applicable, than either blisters or the ointments. They may be employed once or twice daily. The vapour arising from them, and diffusing itself around, has also a direct and beneficial effect, by being inhaled, upon the diseased mucous membrane. M. BROUSSAIS is very favourable to the use of *setons* and *issues*; and I have seen several instances of marked benefit from them, particularly in the obstinate state of the disease which simulates tubercular phthisis. He also recommends warm cataplasms to the chest, made rubefacient by the addition of mustard. I have seen advantage produced by warm bread and water poultices applied over blistered surfaces, and the seats of issues formed by the mezereon bark, and by the same kind of poultices, to each of which one or two table-spoonfuls of the nitro-hydrochloric lotion (F. 834.) had been added. But it is chiefly early in the chronic disease, or when it has recently passed into this state from the acute, that issues and setons prove successful. They exhaust the energies of the system too

much to be of service in the latter stages, or when the discharge from the lungs is profuse, and the vital energies much depressed.

93. *b. Expectorants* have been much employed in this state of disease; and though more appropriate in it, than in the acute, they are often hurtful from their too exciting operation on the vessels of the bronchial surface. This is especially the case with squills, ammoniacum, and senega, which ought to be used with much caution, and never whilst the sputum is purulent, and pain or soreness complained of in the chest, with fever, heat of skin, &c. The best expectorants are those which are also astringent, or at least not very heating: amongst these, the *sulphate of zinc*, with small doses of myrrh or galbanum, and extract of *conium*; or small doses of *sulphate of quinine*, or of the *sulphate of iron*, with *ipeacuanha* and opium; or the *sulphuret of potassium*, and the *balsamum sulphuris* (F. 21, 22.), are the most eligible, when the state of the expectoration, of the skin, and pulse, indicates the propriety of having recourse to tonic expectorants. *Opium* has been too much reprobated in cases of this description, as well as in acute bronchitis, owing to the dogma that it suppresses expectoration. I believe, however, that, when judiciously combined, particularly with *ipeacuanha*, with the chloride of calcium, or either of the sulphates of potash, of alumina, or of zinc; or with the nitrate of potash; or with camphor, with kermes mineral, or the compound powder of antimony, according to the circumstances of the case, it is a valuable medicine; and that the diminution of the expectoration produced by it, and which has been unaccountably dreaded, is, when it occurs, a consequence of its changing the morbid state of the vessels forming the excreted matter. If it be the object — as necessarily follows from the doctrine of some writers — to preserve a copious and free expectoration in this disease, how can it ever be cured? Frequently have I seen this end pursued, as if it constituted all that was required, and squills, ammoniacum, senega, &c. given accordingly; and the more abundant and easy the expectoration thereby produced, the more rapidly did the powers of life give way, or complete hectic, with all its attendants, manifest itself. The following have proved serviceable when the pulse was soft, and not remarkably frequent; the skin cool and moist; the sputum very abundant, and consisting chiefly of mucus; and the weakness and emaciation considerable: —

No. 71. R Pulv. Ipeacuanhæ gr. j.; Camphoræ rasæ gr. ss.—j.; Extr. Conii gr. iv.—vj.; Mucil. Acaciæ q. s. M. Fiat Pil. ij. ter die capiendus.

94. *c.* In cases of this description, any of the

formulæ given under the head *Balsams*, in the Appendix, may be employed. Dr. ARMSTRONG strongly recommended the balsam of copaiva in chronic bronchitis; but it is seldom beneficial, and is certainly inferior to the other balsams and terebinthines in this affection (F. 486, 487, 538, 571.). In the more advanced stages of chronic bronchitis, particularly when colliquative sweats or diarrhoea occur, the most essential benefit has been derived from the following mixture; but even where the bowels are regular, I have found it by no means productive of costiveness. At the time that I was giving this medicine to the third patient on whom I had tried it, a case, showing the success of a nearly similar treatment, was published by Dr. Hastings (*Midland Med. Repos.* vol. ii. p. 376.),—a coincidence fully evincing the propriety of the practice.

No. 77. R Mist. Cretæ ʒjss.; Vini Ipeac. ʒjss.; Tinct. Opii ʒi.; (vel Tinct. Camphoræ Comp. ʒvj.); Syrupi Tolutani ʒij. M. Capiat Cochlearia duo larga ter quaterve in die.

The cretaceous mixture will often be of service when used alone, or with a little of the chloride of calcium, or with the addition of mucilage, or of hyoscyamus, or conium, or extr. lactucæ, or the extr. papaveris, according to circumstances. In this state of the disease, also, I have seen *sulphur* given with advantage in mucilaginous electuaries. Dr. L. KERCKHOFFS states, that he has administered it with success, in conjunction with the powder of the white willow bark. M. BROUSSAIS relies chiefly upon *mucilages* and demulcents, combined with *ipeacuanha* and opium, and certainly with great justice. (See F. 234, *et seq.*) The extr. lactucæ, as recommended by Dr. DUNCAN, may occasionally be substituted for the opium. The decoctions of *Iceland moss*, and the infusions of *conium*, or *marrubium*, of the *uva ursi*, or of the *melissa* (F. 230, 237, 238, 245, 267.), with mucilages, anodynes, and *ipeacuanha*, are also very serviceable. I have given the preparations of *iodine* in a few cases, in small doses; and in some instances, especially when there was little or no febrile action, nor much emaciation, benefit appeared to be derived from them.

95. *d.* When the disease is attended with dyspnoea, and profuse or difficult expectoration, *emetics* are of great, although often of temporary advantage, particularly in aged persons. *Ipeacuanha*, or sulphate of zinc, with the addition of diffusive stimulants (F. 402.), are the most appropriate in the majority of cases. After their operation, and if the strength be not very much reduced, the *digitalis* or *colchicum* may be prescribed, in conjunction with diuretics and gentle astringents (F. 203.). These active medicines are chiefly suited to the more febrile states of the disease, or when soreness or slight pain of chest are complained of, with a puriform expectoration; and are best combined with small doses of blue pill, camphor, and opium,—with pectoral *infusions* and *mixtures* (see App. F. 244, 426, 497.) with demulcents (F. 389.), and with diuretics (F. 194, 195, 236, 237.). Dr. HASTINGS recommends a combination of *digitalis* and *colchicum*; but I have seen more harm than benefit occasioned by it in some cases of chronic bronchitis,—a result which might, *a priori*, be expected from the associated operation of two most depressing medicines, given in a state of disease charac-

terised by irritative, rather than by acute, vascular action. I have found them most beneficial when exhibited singly with diuretics, or diaphoretics, in the chronic form of bronchitis consecutive of exanthematous fevers (§ 54.); sometimes resorting also to the warm bath, followed by frictions of the surface with the liniments F. 297. or 311. The combination of colchicum and digitalis, in small or moderate doses, has proved more serviceable, in my practice, in tubercular disease of the lungs, or when bronchitis has been complicated with tubercles, or with pneumonia. In cases where the propriety of giving these medicines is doubtful, a combination of them with the alkalies, or their carbonates, and with tonic infusions or decoctions, or F. 515—517., or the following, may be prescribed:—

No. 78. R Pulv. Colchici (vel Pulv. Digitalis) gr. j.—ij.; Masse Pilul. Hydrarg. gr. ij.; Masse Pilul. Galbani Comp. gr. v.; Extr. Opii gr. ss.; Syrupi q. s. M. Fiat Pil. ij. bis terve quotidie sumenda.

No. 79. R Infusi Uvae Ursi ʒ xij.; Acidi Sulph. Dil. ℥ xx.; Tinct. Digitalis ℥ x.—xv.; Tinct. Camphoræ Comp. ʒ j.; Syrupi Papaveris ʒ ss. M. Fiat Haustus, bis terve in die sumendus.

No. 80. R Sodæ Carbon. (vel. Liq. Potassæ) ʒ j.; Infusi Calumbæ (vel Decocti Cinchonæ) ʒ vj.; Tinct. Semin. Colchici ʒ j.—ʒ jss.; Tinct. Digitalis ℥ xxx. M. Capiat Coch. ij. larga ter in die.

No. 81. R Mist. Diosmæ Grenatæ (F. 396.) ʒ vss.; Tinct. Digitalis ℥ xxxv. (vel Tinct. Semin. Colchici ʒ j.—ʒ ij.); Extr. Conii gr. xxvj. (vel Extr. Lactucæ ʒ ss.); Syrupi Tolutani ʒ ss. M. Fiat Mist., ejus sumat Coch. ij. larga ter quaterve in die.

96. *Hydrocyanic acid* is often of much service in the chronic forms of bronchitis, especially in their complications with disorder of the digestive organs, and may be exhibited with demulcents, gentle tonics, astringents, or expectorants, or as prescribed in the Appendix (F. 344. 858.) When the disease is associated with derangement of the hepatic functions, or even of the stomach and bowels, it will be necessary to give small doses of blue pill, or of the hydrarg. cum creta, with deobstruents and gentle tonics; and, on some occasions, full doses of calomel from time to time, either alone, or in suitable forms of combination, followed by a purgative.

97. The treatment which has been already recommended for *Humoral ASTHMA* (see particularly § 100, et omn. seq.), and the tonics and astringents, especially the sulphates of zinc, iron, or quinine, already noticed (§ 93.), are applicable, with but little variation, to the more chronic and humoral states of the disease, particularly in persons advanced in life, and in children, when it has assumed a chronic form after whooping-cough and the exanthemata. I have also occasionally seen benefit derived, in these states of chronic bronchitis, from the *chlorate of potash*, given to adults, in from two to six grains, three or four times a day. This medicine was often prescribed by myself and one of my colleagues, at the Infirmary for Children, during the years 1826—1828,

and subsequently, in the more chronic forms of bronchitis, and in various disorders of debility; in which latter it was generally beneficial: but little advantage was frequently derived from it in this disease, unless in those forms of it now mentioned, where it was often of great use, particularly when the morbid action seemed connected with deficient tone of the bronchial vessels, and of the system generally. Mr. MURRAY, in a recent publication, states, that he has employed it successfully in consumption,—a name which has usually comprised most of the cases of this form of bronchitis.

98. *e. Inhalations* of medicated or tar vapours have been recommended by CRICHTON, PAGESFIEBER, HUFELAND, FORBES, HASTINGS, ELLIOTSON, GANNAL, and others noticed in the article on *Asthma*, and been disapproved of by some. I believe that they have frequently been used in too concentrated a state; or too much of the vapour has been diffused in the respired air, occasioning irritation of the bronchial membrane, instead of a gently tonic and healing effect. Whenever any of the vapours advised in this disease produce an increase of the cough, either its use should be left off, or its strength greatly reduced. The manner of having recourse to such vapours, as well as the choice of substances emitting them, have not, in my opinion, always been judicious. The tar vapour is occasionally of service, chiefly from the quantity of turpentine it contains; while the acrid empyreumatic fumes which it also emits, counteract whatever good effect the former constituent might produce. Would it not, therefore, be preferable to try the effects of the substance from which the advantage is obviously derived? I have done so in a few cases of this disease, and seen marked benefit result from it; and therefore recommend it to the notice of other practitioners. In former times, medication by fumigations and vapours was much resorted to; and it is probable, that the early use of incense and various balsamic and aromatic fumes in religious rites had some relation to their prophylactic effect against disease, or even to their curative influence; the more especially as the priests of antiquity also exercised the healing art. In several of the productions attributed to HIPPOCRATES, the inhalation of vapours and fumes of various resinous and balsamic substances is recommended; and a number of writers in the 16th, 17th, and 18th centuries, have advised a nearly similar method, and employed camphor, benzoin, amber, frankincense, myrrh, storax, assafœtida, sulphur, cloves, the balsams, &c. for this purpose. This practice was employed by BENEDICT (see his *Theatrum Tabidorum*) in consumptive diseases; and BOERHAAVE gives several formulæ, in his *Materia Medica*, for fumigations with the above substances. MEAD, in his *Monita et Precepta*, offers several judicious remarks on this subject. He observes—"that fumigation with balsamics, &c., is of vast service in some cases; which is to be done by throwing the ingredients on red coals, and receiving the fumes through a proper tube directed to the wind-pipe." After noticing the undesired neglect of this practice, and the propriety of thus applying medical substances directly to the seat of disease, he states, that the smoke of the balsam of Tolu conveyed into the lungs, or the smoking this substance like tobacco is of signal service in

diseases of this organ (p. 58.). It appears from the writings of FRACASTORI that the fumes of *cinnabar* were much employed by inhalation in the treatment of the constitutional forms of syphilis, at an early period of the history of that disease, when it assumed a pestilential form.

99. Notwithstanding the unsuccessful attempts of BEDDOES to revive the practice, by employing the elementary and permanently elastic gases, but according to views too exclusively chemical, the practice of inhalation has long been neglected or undeservedly fallen into the hands of empirics. Very recently, however, it has been brought again into notice by M. GANNAL, Mr. MURRAY, and Sir C. SCUDAMORE; and *chlorine gas*, the fumes of *iodine*, and watery vapour holding in solution various *narcotics*, have been recommended to be inhaled. I have tried those substances in a few cases of chronic bronchitis; but in not more than two or three cases of tubercular phthisis. The chlorine was used in so diluted a state as not to excite irritation or cough. The sulphuret of iodine, and the *liquor potassii iodidi concentratus* (F. 328.) were also employed; one or two drachms of the latter being added to about a pint of water, at the temperature of 130°, and the fumes inhaled for ten or twelve minutes, twice or thrice daily. The tinctures or extracts of hyoseyamum and conium, with camphor, added to water at about the above temperature, were likewise made trial of; and, although the cases have been few in which these substances have been thus used by me, yet sufficient evidence of advantage has been furnished to warrant the recommendation of them in this state of the disease.

100. *Inhalations* also of the fumes of the *balsams*, of the *terebinthinates*, of the odoriferous *resins*, &c., are evidently, from what I have seen of their effects, of much service in the chronic forms of bronchitis: and I believe that they have fallen into disuse, from having been inhaled as they arise in a column or current from the substances yielding them, and before they have been sufficiently diffused in the air. When thus employed, they not only occasion too great excitement of the bronchial surface, but also intercept an equal portion of respirable air, and thereby interfere with the already sufficiently impeded function of respiration. M. Nysten has shown (*Dict. des Scien. Méd.* t. xvii. p. 143) that ammoniacal and other stimulating fumes, when inhaled into the lungs in too concentrated a state, produce most acute inflammation of the air-tubes, generally terminating in death; and has referred to a case in which he observed this result from an incautious trial of this practice. I conceive, therefore, that the vapours emitted by the more fluid balsams, terebinthines, the resins, camphor, vinegar, &c., and from chlorine and the preparations of iodine, should be more diluted by admixture with the atmosphere, previously to being inhaled, than they usually are. According to this view, I have directed them to be diffused in the air of the patient's apartment, regulating the quantity of the fumes, the continuance of the process, and the frequency of its repetition, by the effects produced on the cough, on the quantity and state of the sputa, and on the respiration. The objects had in view have been gradually to diminish the quantity of the sputum, by changing

the action of the vessels secreting it; without exciting cough, or increasing the tightness of the chest, or otherwise disordering respiration. From this it will appear, that the prolonged respiration of air containing a weak dose of medicated fumes or vapours, is to be preferred to a short inhalation of them in their more concentrated states. The want of success which Dr. HASTINGS and others have experienced, evidently has been partly owing to the mode of administering them, and partly to having prescribed them inappropriately. When the patient complains of acute pain in any part of the chest, as in some of Dr. HASTINGS' cases, they are as likely to be mischievous as beneficial. Where benefit has been obtained, it will be found that it was when the fumes of the more stimulating of those substances were diffused, in moderate quantity, in the air of the patient's apartments; or when he passed, at several periods daily, some time in a room moderately charged with the vapour or fumes of the substance or substances selected for use. (*See the remarks on Inhalation in Humoral ASTHMA*, § 88., for an account of various medicines that may be employed in this manner.)

101. *f. Sponging the surface of the chest*, and trunk of the body, first with tepid, and afterwards with cold lotions, has often been practised by me with advantage in several states of this disease. When the expectoration has been profuse, the debility great, and little or no febrile heat present, I have preferred for this purpose the nitro-hydrochloric acid lotion (F. 834.), in a warm or tepid state, night or morning, or both. When the disease is more active, the habit of body being, nevertheless, relaxed and debilitated, a solution of common salt in water, or the lotion, R. 54., seems preferable; and the directions given respecting this treatment in the article *ASTHMA* (§§ 116, 117.) should be strictly followed. I have observed much benefit derived from the application, for a considerable time, of one of the plasters, F. 111, 115, 118, 119., between the shoulders; whilst cold sponging the anterior of the trunk with the lotions referred to has also been directed.

102. *g. The complications of chronic bronchitis* require generally no particular modification of treatment from that now detailed: indeed, some of them have been already noticed. I may, however, add, that, in the chronic asthenic states of the disease frequently met with in aged persons, and often occurring in children after exanthematous diseases, whooping-cough, and bowel complaints, the flowers of sulphur, the preparations of zinc, the trisnitrate of bismuth, and the chlorates of potash and of lime, have severally been of great service, especially when combined with narcotics—with opium in the aged, and conium in the young,—their constipating effects upon the bowels being duly obviated by the occasional exhibition of purgatives. The chronic bronchitis complicated with, or consecutive of, whooping-cough, the characteristic cough of the latter either still continuing, or having altogether disappeared, is frequently attended with dilatation of the bronchi. In these cases, balsams, inhalation, the use of tonics, particularly the sulphate of iron, quinine, the liniments already noticed, frequent doses of sulphur, or moderate doses of

the chlorate of potash, are required. If the child be not very young, either of these latter may be combined with belladonna, or with conium, and given in honey or syrup of squills; or with simple syrup, sugar, powdered liquorice-root, or with the compound tragacanth powder. When the disease is associated with chronic irritation of the mucous surface of the bowels, the chlorate of lime will be of much service, and will soon restrain the latter affection; the use of the *liniments* already recommended (F. 296. 311.) in addition, generally contributing to cure the bronchial disease. Either of these liniments has often been sufficient of itself to remove all disorder, both in the consecutive states, and in the different complications noticed at this place; and, when bronchitis seems to have a tendency to terminate, or has actually terminated, in effusion, they have powerfully assisted the treatment. When, however, dropsies supervene, in addition to them, colchicum or digitalis, with astringent tonics; squills, with blue pill, taraxacum, or extract of sarsaparilla; the preparations of *iodine*, alone or with narcotics; bi-tartrate of potash, with the bi-borate of soda, particularly this last; and various other diuretic and deobstruent medicines in different forms of combination—of which numerous examples are given in the *Appendix*—and the general plan of treatment recommended in the article *Dropsy*; should be employed.

103. *C. The regimenal treatment of bronchitis requires strict attention.*—*a.* In the *sthenic acute* disease it should be strictly antiphlogistic; and, at the commencement of convalescence, a farinaceous diet adopted, until out-of-door exercise may be taken, or shortly before. In the *asthenic states* of acute bronchitis, this regimen is chiefly applicable to the commencement of the disease: subsequently, nourishment in small quantities, suited, in kind and frequency of partaking of it, to the state of the symptoms, the powers of the digestive organs, and feelings of the patient, should be permitted; and even animal food of a digestible nature, in moderate quantity, may in some cases, particularly in the aged, be permitted once a day. The decoction of Iceland moss, jellies, mucilaginous and emollient soups; shell-fish; the different kinds of white fish, dressed either with sweet oil or the oil obtained by boiling their fresh livers; the lighter kinds of animal food; and, in the case of infants, attention to the milk of the mother, or a healthy wet-nurse; are all occasionally of service during early convalescence from the *acute* forms of bronchitis, and in the progress of the more febrile states of the *chronic* disease. In the more *asthenic* cases of this latter, or when the expectoration is profuse, the skin cool and moist, and the habit of body lymphatic, relaxed, or wasted, animal food, especially fresh beef or mutton, underdone, and in moderate quantity; new-laid raw eggs; or a due proportion of digestible and stimulating food; will be found most serviceable. In nearly all the *chronic* states of the disease, particularly in their advanced stages, a light nutritious diet is necessary.

104. *b.* The patient's *beverage* should receive particular attention. Lemonade, imperial, barley-water, and the cooling and aperient drinks prescribed in the *Appendix* (F. 588—595. 916.), should be employed in the *sthenic* form of the acute disease. In the *asthenic* and *chronic* states,

the red Bordeaux wines, or the wines of Burgundy—the former generally reduced by one third or one half water; or beer or ale, also reduced, to which a little of the liquor potassæ, or of Brandish's alkaline solution, has been added, may also be tried at meals; and either of these, or of the more cooling beverages, adopted, that may be found to agree best with the patient. If the disease evince a disposition to terminate in dropsy, the imperial drink, with the addition of a little bi-borate of soda, or F. 590, 591., will be most serviceable. In the advanced period of *chronic*, or during convalescence from *acute*, bronchitis, the sulphureous mineral waters will often be beneficial. Those of Harrowgate, Leamington, or Moffat, may be tried; or of Enghien, Bonnes, Barèges, or Cauterets (Rocne); or the artificial waters of Ems or Carlsbad.

105. *c.* Few diseases are more benefited than chronic bronchitis by *change of air*. A residence on the southern coast, particularly at Torquay, and in various other parts of Devonshire, during the winter and spring months, guarding against vicissitudes of climate,—which, however, is milder and less variable in this part of the island than any where else; wearing flannel next the skin, especially during winter and spring; gentle exercise on horseback, or the use of the swing; and constant attention to the state of the bowels; are severally of great importance. During the progress of convalescence, as well as in the earlier stages of disease, particularly if the secretion from the bronchi continue, it will be necessary to resort occasionally to an emetic; and in a day or two subsequently, notwithstanding the bowels may be freely open, to an active cathartic. In these cases, the addition of a vegetable bitter or tonic to a purgative medicine,—as the sulphate of quinine to aloes, or the infusion or extract of gentian to senna,—will have a decidedly cathartic operation, without lowering the energies of the frame. There are few diseases more benefited, either in their progress or decline, than those now discussed, by active purging; but it will often be requisite to combine the purgatives with stimulants or tonics, in order that an active or continued operation on the bowels may not exhaust the patient. During convalescence, the free use of purgatives requires a liberal and invigorating diet.

106. *V. DILATATION OF THE BRONCHI.*—*i.* The *anatomical characters* and *physical signs* of this change of the bronchi have been already described (§ 19.). It is almost entirely a consequence, of an attendant upon, the more chronic cases of bronchitis, or of whooping-cough complicated with bronchitis. The expectoration, besides being copious and puriform, is often fetid,—a diagnostic symptom of this alteration, without which, M. Louis, and other pathologists, who have devoted much attention to pulmonary diseases, have sometimes failed of distinguishing it from phthisis.

107. *ii.* The *TREATMENT* of this alteration is nearly the same as that which has been recommended in the more chronic states of bronchitis. The means which are especially indicated consist of the *inhalation* of balsamic and terebinthinate fumes; of those of creosote, chlorine, iodine, &c. (§§ 99, 100.); the internal use of balsams, tonics, and bitters, particularly the sulphates of quinine, or of zinc, or iron;

and other preparations of cinchona or steel; with the use of the liniments already noticed (§ 102.); or the nitro-hydrochloric acid lotion on the chest. The chlorate of potash, or of lime, seems indicated in this form of the disease. An open state of the bowels, an occasional cathartic, nutritious diet, and change of air, are also evidently required. In other respects, the treatment already detailed (§ 101. *et seq.*) may be followed; or modified, according to the peculiarities of the case.

103. VI. ULCERATION OF THE BRONCHI (see §§ 7, 8.) is another alteration which is produced by, or is attendant on the advanced stages of, chronic bronchitis; most frequently, however, when complicated with tubercular phthisis. It is not infrequently met with, particularly after bronchitis occasioned by the mechanical irritation of mineral, vegetable, or animal molecules. The existence of ulceration, when seated in the bronchi, is not indicated by any sign in addition to those which accompany the most chronic states of bronchitis, or tubercular disease, when it arises from, or is complicated with, this change. When affecting the LARYNX or TRACHEA (see these articles), it may frequently be suspected, or occasionally prognosticated. In a case which occurred in the trachea, a prognosis to this effect was given by me long before death.

109. The TREATMENT of this lesion, even could its existence be ascertained during life, cannot be different from that required in some other states of chronic bronchitis. That ulceration may take place in the bronchi, and heal, as evinced by the appearance of cicatrices, has been ascertained by M. LAENNEC, and other pathologists. In addition to the means of cure already described, the establishment of local drains of the most active kind is obviously required. Blisters and issues applied to a distant part have not been found of use by M. LAENNEC. He prefers the repeated application of small moxas as near the seat of disease as possible, and the preservation of absolute rest and silence. The inhalation of emollient, anodyne, and balsamic vapours and fumes may likewise be tried; and, if the disease be devoid of marked febrile excitement, the expectoration abundant, and the powers of life consequently reduced, the treatment advised for dilatation of the bronchi (§ 19.) may be employed in all its parts. (For the treatment of other organic changes of the air-passages, see arts. CROUP, LARYNX, LUNGS—*Hæmorrhage from, and TRACHEA.*)

VII. BRONCHIAL FLUX.—*Bronchorrhœa* (from *ῥόγγος* and *ῥεω*).—*SYN.* *Bronchorrhœe* (Roche); *Catarrhe Pituiteux* (Laennec); *Mucous Flux*.

CLASSIF. I. CLASS, III. ORDER (*Author*).

110. DEFIN. *A flux of watery mucus, or phlegm, from the chest, with more or less cough, but without fever; frequently occasioning exhaustion.*

111. This affection varies considerably. It is often a variety of chronic bronchitis; being consecutive of it in persons advanced in life, or those of a relaxed and phlegmatic or pituitous habit of body. In other cases it appears from the commencement, or consecutively of slight catarrh, as intermediate between chronic bronchitis and humoral asthma. This appellation may, upon the whole, therefore, be viewed as applicable to those cases which are attended with a more

abundant, fluid, and transparent expectoration, than is observed in chronic bronchitis, and are devoid of fever and all other signs of inflammatory action; whilst they are equally without the severe dyspnoea, the paroxysms of suffocation and cough, and the intermissions, characterising humid asthma.

112. i. *Bronchorrhœa* proceeds generally from similar causes to those which produce common catarrh, or bronchitis, even although it be not consecutive of some one of the forms of bronchial inflammation. It is very frequently, either at its commencement, or recurrence, connected with cold and moist states of the atmosphere, or occasioned by exposure to cold in some one or other of its forms. When it occurs as a sequela of bronchitis, it may be viewed as arising from lost tone of the vessels and of the bronchial surface, the flux or determination to this part still continuing, from peculiarity of habit or some other cause, after all inflammatory and febrile symptoms have been removed. Thus, it is very frequent in aged persons of relaxed fibres, who have experienced repeated attacks of pulmonary catarrh.

113. ii. *Diagnostic Symptoms.*—*Bronchorrhœa* may be distinguished from chronic bronchitis, tubercular phthisis, and humoral asthma, by the following characters:—The quantity of fluid expectorated is very great; being, in some cases, as much as four or five pounds in the twenty-four hours. The sputum is colourless, ropy, transparent, slightly frothy on the surface, and resembling the white of egg mixed with water. It is without the thickened sputa generally accompanying chronic bronchitis. There is considerable dyspnoea, but the chest sounds well throughout upon percussion; and the cough is slight comparatively to the quantity of the expectoration, being evidently no more than is occasioned by the discharge of the secreted fluid. The pulse and temperature of the skin are natural, and there are no night sweats. The appetite is generally unimpaired; and emaciation is not remarkable, or not at all observed, unless the quantity of the sputum be extremely great. M. NAUCHE states, that the expectoration in this state of disease is always more or less acid, and reddens litmus paper, whilst that proceeding from inflammatory action restores the blue tint to this paper after being reddened by acids. *On auscultation*, the respiratory murmur is commonly weak, but is very rarely suspended. The sibilous rhonchus is heard more or less distinctly, and often mixed with the sonorous, and occasionally with the mucous rhonchus, the bubbles of which seem to burst upon the surface of a fluid of less consistence than in bronchitis.

114. *Bronchorrhœa* usually commences with catarrhal symptoms, and frequently without fever. In other cases, after bronchitis has continued chronic for a longer or shorter period, the expectoration becomes less consistent and less opaque, more abundant, and similar to that described; and the affection becomes established, —aggravated at times by disorder of the stomach or bowels, or by changes of the air, especially by cold and moisture, or by arrest of the cutaneous transpiration from any cause,—and ameliorated at other times by a warm dry air, an open state of the bowels, and light nourishing diet, taken in

moderate quantity. Vacillating in this manner, the disease may continue for years if it be not severe, without materially affecting the strength. But more frequently the discharge increases, after irregularly prolonged, and more or less slight intervals; the patient loses his flesh, and becomes paler; his strength is impaired; dyspnoea increases; and, in some cases, the affection either runs into humoral asthma, or the quantity of expectoration is augmented so as to exhaust his energies, and to occasion suffocating paroxysms of cough. In rarer cases, the quantity of the bronchial discharge has been so great as to occasion the exhaustion and death of the patient. M. ANDRAL has detailed two cases of this description, wherein, upon dissection, no evidence of inflammation or congestion could be found in the air-tubes. M. ROCHE has described, what he has designated an acute form of this affection, which other French pathologists have named *catarrhe suffocant*; but it differs in no respects from the more humoral states of asthma, described in its more appropriate place, and presenting all the symptoms of spasm of the air-passages, with a copious viscid expectoration; the spasm and other symptoms subsiding after the bronchi and trachea are unloaded of the secretion accumulated in them. Bronchorrhoea has, in rare instances, been the means of removing other diseases. M. ANDRAL states that he has seen hydrothorax disappear after the establishment of a copious bronchial flux.

115. iii. TREATMENT.—After the full exposition that has been given of the means of cure in the different states of chronic bronchitis, to some of which bronchorrhoea is closely allied, it will be sufficient to enumerate succinctly the various means which are applicable to this affection. As the disease essentially consists of an increased secretion and exhalation from the respiratory mucous membrane, with a determination of the circulation to that quarter, and deficient tone of the vessels distributed to it, the obvious indications are, to increase the secretions from other surfaces and organs, thereby to derive from the lungs, and to restore the lost tone of this membrane and its vessels. In some cases, accordingly, it will be advantageous to commence with an ipecacuanha or sulphate of zinc *emetic*, and afterwards to act freely upon the secretions and alvine excretions by purgatives. I have never seen a case of the disease which has not been much relieved by purgatives; taking care, however, that they should not lower the energies of the constitution, by combining them with tonics, bitters, or stimulants, and allowing sufficient light nourishment to admit of this mode of derivation being satisfactorily employed. In the intervals between the exhibition of purgatives, diuretics and diaphoretics may be exhibited, and the cutaneous functions promoted by wearing flannel next the skin during the winter and spring months.

116. *Expectorants* are very much employed in this affection; but some of this class of medicines are seldom of benefit in it, unless combined with opium. The *balsams* and *terebinthinates* (F. 484—487, 489.); the sulphate of zinc, with myrrh, or the compound galbanum pill; and either of these, with camphor and opium; are often of service. In addition to these, *inhalations*,

as recommended in another part (§§ 99, 100.), may be employed. Although astringents and inhalations are often required, yet we should be cautious in using them when the disease has been of very long continuance, particularly in persons advanced in age, or when there is any irregularity of the action of the heart, or physical sign of organic change about this organ, complicated with it; inasmuch as the arrest of an habitual discharge will, in such circumstances, risk the supervention of effusion in the cavities of the thorax. It will be more judicious, in these cases, to confide in purgatives combined with bitter tonics; in diuretics, and in diaphoretics, so as to moderate the discharge, and prevent its increase, or its exhausting effects upon the system. At the same time the vital energies should be promoted by a light nutritious diet, moderate exercise, and change of air, with the sulphureous or gently tonic mineral waters. In other cases, where the age of the patient, the regular or healthy state of the heart's action, the absence of leucophlegmosia, and the circumstances of the case altogether, are such as to preclude dread of the consequences of suppressing this discharge, cold sponging the surface of the body by the nitro-hydrochloric lotion, &c. (§ 101.), and the liniments already noticed (F. 296, 311.), with the internal use of the more astringent tonics, particularly the sulphate of iron or of quinine, in addition to the measures already recommended, may also be practised.

BRONCHOCELE (from *Βρόγχος*, throat, and *κῆλη*, a swelling). SYN. *Hernia Cytivalis*, *Gossum*, *Luftröhrenbruch*, *Kropf*, Ger. *Goitre*, Fr. *Ironcocele*, *Gozzo*, Ital. *Thyrophraxia*, Alibert. *Cynanche Thyroidea*, Conradi. *Goitre*, “*Derbyshire Neck*.”

CLASSIF. 4. *Class*, Local Diseases; 6. *Order*, Tumours (*Cullen*). 6. *Class*, Excrement Function; 1. *Order*, Affecting the Parenchyma (*Good*). IV. CLASS, IV. ORDER (*Author*, see *Preface*).

1. DEFIN. Chronic enlargement of the thyroid gland, sometimes with change in the surrounding parts, generally increasing slowly, often continuing for years, and depending upon constitutional causes.

2. I. CAUSES, AND MORBID RELATIONS.—This disease is endemic in Derbyshire, and some other parts of this country; but most remarkably so in Switzerland, various adjoining districts, and in some places in South America. It usually occurs during the early epochs of life, most frequently about the period of puberty, in persons of a weak and lax fibre, and generally in females; it very seldom being observed in Great Britain in males; but the comparative frequency of it in the latter sex is greater in Switzerland, and other parts where it is very prevalent, and is connected with cretinism. In a considerable number of cases which have come before me in females, I have never met with any before the period of commencing puberty,—not even at the Infirmary for Children; although the menses have often been delayed for a year or two, or even longer, when the tumour has appeared at this epoch; and I have seldom observed an instance in this sex unconnected with some kind of irregularity of the menstrual discharge, or disorder of the uterine functions. In two cases, occurring in married females, who were under my care, unhealthy or irregular menstruation had existed during the continuance of the goitre; in one case for eight years, in the other for five; upon its disappearance, pregnancy took place in both. Suppression of the menses has sometimes caused its sudden appearance and rapid development; and it more rarely has originated during pregnancy and the puerperal states. Authors have adduced conclusive proofs of its occurrence hereditarily, independently of endemic influence.

3. Dr. Good has attributed the disease, in a great measure, to poverty, and the nature of the food: the rich being exempt from it. This is, however, very far from being the case. I have seen several cases of bronchocele in the richest of this metropolis. He is also wrong in attributing it to the use, in Derbyshire, of *oaten cakes*. In Scotland, where this article of diet is in general use, bronchocele is rare.

4. That it chiefly depends upon certain physical causes is shown by its prevalence in certain districts in preference to others, and by the circumstance of its disappearance when persons affected by it endemically have changed their

residence. M. ALIBERT mentions his having seen it disappear after a residence in Paris. It has been very generally imputed to the water used by those affected. Since the time of PLINY, it has been attributed to the use of snow water. But it prevails in several places where this cause does not exist, as in Samatra, and several parts of South America. The Swiss who drink snow water are free from the disease, while those who use hard spring water are most commonly affected. Captain FRANKLIN states, that at a part in his journey to the Polar Sea, where bronchocele prevails, it is confined to those who drink river water, and that those who use melted snow escape. Mr. BALLY ascribes its frequency, in a district in Switzerland, to the use of spring water impregnated with calcareous or mineral substances; and he states, that those who use not this water are free from both goitre and cretinism. Dr. COINDET observed that the inhabitants of Geneva, who drink the hard pump waters, are those most liable to bronchocele. Its prevalence in Nottingham is ascribed by Dr. MANSON to the same cause; which also seems to occasion it in Sussex and Hampshire, in the valleys of which counties it is frequently met with.

5. That this is, however, not the only cause, may be inferred from other physical circumstances connected with its endemic prevalence. Its great frequency in low, moist, marshy, and warm valleys, and the exemption of the inhabitants of dry and elevated situations, have been shown by LARRY, FODÉRÉ, SAUSSURE, REEVES, CLARK, VALENTIN, POSTIGLIONE, and J. JOHNSON, as respects various districts in Switzerland, the Tyrol, Carinthia, the Vallais, and the north of Italy. Similar facts have been adduced by Dr. GIBSON, and HUMBOLDT, in regard to the United States, and South America. It is most probable, however, that the exhalations from the soil of those localities are not the only, but a concurrent cause, co-operating with others possessing equal influence in the production of the disease, and particularly with the nature of the water. But it as certainly sometimes appears where neither of those causes can be traced, as in London; disorder of some kind in the uterine functions being the most frequent morbid relation it has presented, as far as my experience has gone. Its connection with cretinism in the districts on the Continent above alluded to, and the occasional appearance of the disease at very early periods of life—it being even sometimes congenital, in these countries, as well as being more common there in the male sex than in this country—are matters of some interest, and not readily admitting of explanation; since poverty, close, confined, and ill-ventilated apartments, are not the chief causes of those phenomena, as shown by their absence in the poorest classes in this metropolis. Dr. PARRY has seen goitre follow diseases of the heart, and epilepsy. FLAJANI has noticed the common occurrence of palpitations and affections of the lungs from the disorder it has occasioned of the respiratory function. When the tumour is very large, or hard, or when it has increased suddenly, it not infrequently occasions most urgent symptoms, by its pressure on the trachea, œsophagus, and jugular veins.

6. As respects the external and internal appear-

ances of this tumour, I may briefly observe that it affects generally the whole gland; but is also sometimes confined to the lateral or to the middle lobes: it is more rarely large on one side than another. At first it is commonly compact, rounded and equal; but, as it increases, it is either soft and flabby to the touch, or unequal, irregular, hard, and obscurely lobulated. It is usually free from pain, and is not discoloured. When it is greatly increased in size, and is soft, it appears pendulous, chiefly owing to its lower parts being most enlarged. When the tumour is divided, the cells of the gland are found, according to HUNTER, BAILLIE, and B. BELL, filled with a more or less viscid fluid; and are of various sizes, generally from that of a pea downwards, not only in different cases, but even in the same gland. In the older, harder, and more irregular forms of the tumour, melicerous, steatomatous, cartilaginous, and ossific deposits have been met with in parts of it, by CELSUS, DE HAEN, FREYTAG, GIRAUD, HEDENUS, and others. The usual state in which this disease presents itself, obviously, is that of an increased secretion into the cells of the gland, distending them more or less; the other changes sometimes observed, being consequences of obscure irritation induced in parts of it during its continuance or growth.

7. II. DIAGNOSIS.—It is necessary to be aware that other diseases of either a more acute or malignant character may affect the thyroid gland and its vicinity, and be mistaken for bronchocele. 1st, The gland may be either healthy, or but little enlarged; the tumour consisting chiefly of thickened surrounding cellular tissue, sometimes containing cysts filled either with a serous, albuminous, or purulent matter. Large *encysted tumours* may also form in the course of the trachea. But these may be readily distinguished by their situation, form, and fluctuation. 2d, The gland itself may be the seat of *chronic or acute inflammation*. In this case the swelling increases more rapidly, but seldom attains a large size; and is generally attended by redness of its surface, and increased temperature. It is also painful, particularly on pressure, and is very hard. I lately saw a case of this description in a married female of about thirty, who was also seen by Mr. LLOYD, where the inflammation had proceeded to suppuration, and had terminated in an external opening. I believe that inflammation of the gland never occurs but in scrofulous habits. 3d, The gland may also be the seat of *scirrhus*, which may ultimately go on to carcinomatous ulceration; but this is a rare occurrence. In this case the gland is very hard, seldom large, sometimes scarcely increased in bulk, and is the seat of sharp darting pains. It is only met with in persons advanced in age. ALIBERT states, that he has observed a case of goitre pass into cancer; but I doubt the fact; cancer having a very wide and indeterminate signification with this writer. The disease can scarcely be mistaken for aneurism of any of the thyroidal arteries, if any share of attention be directed to the subject. Bronchocele has been considered in the light of a strumous disease—as a form of scrofula. Dr. POSTIGLIONE, however, contends that no connection exists between these diseases. As respects the state of morbid action in the gland, the concomitant phenomena, and the respective terminations

of both diseases, there is certainly no intimate relation between them.

8. III. TREATMENT.—Previous to the use of iodine in the cure of bronchocele, numerous remedial means were recommended by writers. Of these, the most common were frictions with various liniments; dry rubbing; stimulating and astringent lotions; cold bathing, and cold douches; mercurial applications; plasters with cicuta and ammoniacum, or with ammoniacum and hydrarg.; repeated blistering; leeches applied to the tumour; electricity and galvanism; moxas, issues, and setons; ligature of the arteries supplying the gland; and extirpation of the gland itself. Amongst the internal remedies recommended, I may notice the various preparations of mercury; digitalis combined with camphor (OSSIANDER); sulphuret of potassium; chloride of barium (POSTIGLIONE); cicuta or belladonna, either alone, or with the chloride of barium; the chloride of calcium; preparations of potash and soda; various mineral springs; the use of sea water, and of distilled water; the ammonio-chloride of iron; burnt sponge, given either alone, or with mercury; and the ashes of the *fungus vesiculosus* (RUSSELL).

9. Of all these, the most celebrated was burnt sponge; and, after the discovery of *iodine*, this substance, which, having been found by Dr. STRAUB, of Berne, to be contained in official sponge, was recommended by him in 1829, and adopted by Dr. COINDET, of Geneva: and so successful has this medicine proved in the treatment of bronchocele, that of a hundred and twenty cases treated with it by Dr. MANSON, of Nottingham, seventy-nine were cured, eleven greatly relieved, and two only were not benefited by it. Of several cases of the disease which have come before me since the introduction of this remedy into practice, there has not been one which has not either been cured or remarkably improved by it. I believe, however, that although it has been found the most certainly beneficial of any medicine ever employed in bronchocele, some other practitioners have not derived an equally uniform advantage from its use. I can account for this only by considering that it has been given in too large and irritating doses, or in an improper form; and without due attention having been paid to certain morbid and constitutional relations of the disease during the treatment. The cases of two females who were lately completely cured by the remedy confirm this inference. They had both had the tumour for several years, one for nine years; and had, on former occasions, gone through long courses of iodine, prescribed by judicious and eminent practitioners, but without advantage. When this medicine was ordered by me, it was, therefore, with great difficulty that they were induced to have recourse to it again. It was ordered in very small doses, often repeated, and strict attention was paid to the state of the secretions, and to the uterine functions. In the course of a fortnight an improvement was manifest; and of a few weeks longer, a great decrease of the tumours had taken place. One of these females, a married woman, who had been once pregnant nine years before, upon the disappearance of the tumour came with child; soon after which it somewhat suddenly reappeared, but the resumption of the iodine again dispersed it. The preparations given

in the Appendix (F. 204. 277, 278. 302. 323, 324.) are those which an extensive experience of its effects in various diseases, as well as in this, has led me to adopt.

10. In respect of the use of iodine in bronchocele, the weaker preparations should be at first preferred; and care should be taken never to exhibit them to the extent of irritating the stomach or bowels; when this effect is produced, little or no benefit will be derived from them. The success which Dr. MANSON and M. LUGOL have derived from this valuable medicine, I know from experience to be chiefly owing to the small and soluble doses in which they exhibited it. In some of the more obstinate cases, it will be often requisite to assist the operation of iodine by other means. Sometimes the occasional use of emmenagogue aperients will be of much service; and when the uterine functions evince disorder, as they very frequently do in cases occurring in females, I have usually directed either the bi-borate of soda, or milk of sulphur, to be taken, in the form of electuary, every night (F. 89. 281.). A calomel purge will also be sometimes of service. I have generally preferred the internal to the external use of the medicine in this disease. In some more obstinate cases, they may be both employed; but its external application should be of the mildest kind. In some cases, a moderate blood-letting may be premised; and some writers recommend that leeches should be applied to the tumour itself. Nearly all the cases which I have seen, having occurred in females, in whom it appeared requisite either to promote the menstrual discharge or to subdue uterine irritation, I have usually directed the bleeding, when practised, to be performed in the feet, or leeches to be applied to the groins. Dr. COSTER has adduced a case in which galvanism materially assisted the iodine in removing bronchocele.

11. Dr. KOLLEY has stated, that iodine should not be exhibited where there is a disposition to congestion in the head and internal viscera; when febrile and inflammatory symptoms are present; when gastric, hepatic, or intestinal disorder exists; and when there is a disposition either to hydrocephalus or to pulmonary consumption. This is in some respects just; but after depletions, and when the more marked symptoms of these disorders are subdued, iodine may, notwithstanding, be exhibited, if its effects be carefully watched, and if the mildest and weakest preparations be selected, and these be combined with anodynes and narcotics. I have observed that a continued course of iodine has sometimes had the effect, particularly during cold weather, of producing pains in the limbs or joints resembling rheumatism, which have continued to increase if the medicine was not for a time relinquished. This effect has never appeared during a course of less than six weeks. It has generally soon disappeared after an aperient operation from sulphur, and one or two warm baths. A change to warm weather has also removed it.

12. If iodine fail of reducing the tumour, and if its pressure occasion urgent symptoms, recourse must be had to surgical aid. For a full exposition of this part of the treatment, I must refer the reader to Mr. COOPER'S *Surgical Dictionary*, and limit myself to a brief enumeration of this class of measures. The first and most important of

these is the insertion of setons in the tumour. This practice was recommended by Dr. QUADRI, of Naples; and practised first in this country by Mr. COPLAND HUTCHISON, and with success. According, however, to the experience of Mr. JAMES, Mr. COOPER, and Mr. GUNNING, this practice is liable to occasion dangerous hæmorrhage, sloughing of the tumour, and irritation and inflammation of the trachea or larynx. Mr. LYFORD has, however, employed setons, successfully; whilst HEDENUS states, that he has seen tetanus occasioned by their introduction. It has been recommended to cut off the supply of blood to the gland by tying its arteries; and the advice has been followed by BLIZARD, WALTHER, COATES, BRODIE, and EARLE. The cases thus treated by BLIZARD, COATES, and BRODIE, terminated unfavourably; whilst those by WALTHER and EARLE, succeeded. Lastly, the tumour has been altogether removed by excision. DESSAULT first performed this operation successfully; GOOCH attempted it in two cases, but failed; DUPUYTREN and KLEIN also failed; whilst VOGEL, THEDEN, and GRAEFFE, performed it with success; and HEDENUS, of Dresden, succeeded in six cases in which he resorted to this operation.

CLASSIF. 6. Class, 3. Order (GOOD). 4. Order (Willan). IV. CLASS, IV. ORDER (Author).

I. DEFIN. An eruption of large vesicles containing a serous or sero-puriform fluid; frequently succeeded by yellowish or yellowish brown scabs, and sometimes by ulcerations.

2. PLENCK first separated the individual eruptions belonging to this order from the vesicular

eruptions, to which they are intimately related, and formed them into a distinct class. WILLAN afterwards adopted a nearly similar arrangement, comprising under this head erysipelas, but leaving out rupia. M. BIETT has, however, with stricter propriety, excluded from it the former disease, and introduced the latter. Adopting, therefore, his classification, this order of eruptions embrace pemphigus, pompholyx, and rupia. These forms of bullæ proceed from internal causes; but various irritants, applied externally, will also give rise to a similar eruption. The influence of cantharides and other rubefacients, of excessive heat or cold, of friction, of poisons, &c., in occasioning vesications, is well known. In a pathological point of view, both the bullæ produced by internal causes, and the vesications formed by external causes, depend upon very nearly the same state of the *rete mucosum*. This tissue is more or less inflamed, or affected in such a way as to secrete a greater quantity of serous fluid than can be exhaled through the cuticle, which is thereby separated from the vascular tissue, and, by the increase of this fluid, elevated into blisters, or bullæ, of various dimensions.

3. The eruptions of this class are both acute and chronic. The parts affected are often preceded by more or less redness, and occasionally by a very slight elevation. But, in many instances, no such inflammatory appearances are observed before the serous effusion beneath the cuticle takes place. After an indefinite period, varying from a few hours to four and twenty, a small vesicle appears, and gradually enlarges, until it reaches, generally within eight and forty hours, a great size. The bullæ thus formed are at first tense, and the fluid contained in them serous and transparent; but it sometimes becomes, especially at a later stage, sero-purulent, and rarely sero-sanguineous. After an uncertain time the bullæ pass from a tense to a flaccid state, the included fluid, at the same time, assuming a very slightly opaque and thickened condition. If they be situated where the epidermis is very thin, or occur in very young infants, they often break before this change in the fluid takes place. But where they are more persistent, the humour becomes thicker, and often forms scabs of a light yellowish colour. The affected parts of the skin are afterwards either provided with a new cuticle, or are affected with more or less severe ulceration. Bullæ may thus appear in any part of the surface, and even in the scalp, and be more or less numerous, or thickly scattered over the body. I have observed them so extensive, as respects both number and size, as to occasion death, obviously from the constitutional disturbance and irritation resulting from the loss of the cuticle over more than two-thirds of the whole surface of the body.

4. These eruptions are also either idiopathic or symptomatic — most frequently the latter. They may also be infectious, or dependent upon the air of a hospital. Thus I have seen them prevail (chiefly in the form of pemphigus) at one time, in Queen Charlotte's Lying-in Hospital, to the extent of affecting nearly all the infants born there during several months, notwithstanding fumigation and whitewashing were resorted to; no other disease having occurred there during that period. In a chronic state, they are usually symptomatic of irritation or other disor-

der of the digestive organs, more especially of the alimentary canal; of chronic bronchitis, and of general cachexy. They are sometimes observed as an attendant upon small pox, and very rarely in the other exanthemata.

CLASSIF. Constitutes the 3d Class in Dr. *Cullen's* Nosology; and the 4th Order in the Class, Diseases of the Sanguineous Function, in Dr. *Good's* Arrangement. I. CLASS, V. ORDER (*Author*, see *Preface*).

1. DEFIN. *Depravity of the constitution, without fever, affecting more or less the solids, the circulating fluids, and the secretions.*

2. i. SYMPTOMS.—The chief characteristics of this state are, want of vigour and vital cohesion of the soft solids, with defective digestion and assimilation, diminished animal warmth, universal languor, and deficient strength or activity. The skin is usually pale, yellowish, or lurid; and the white of the eyes in some cases almost transparent. As this state advances, the countenance becomes pale, white, or bloated; the skin loses its vital tint, and changes either to a dirty white, or to a yellow hue. The muscles are flaccid, and deprived of their healthy elasticity; the mind is inactive; the breathing difficult upon exertion; the feet and ankles swollen; the pulse slow and soft; the eyelids œdematous; the urine turbid; the alvine evacuations irregular and offensive; the sleep oppressed, and all the vital manifestations are enfeebled and languid. In females, more or less of these symptoms are associated with suppressed, retained, morbid, or irregular menstruation; pains in the forehead, back, loins, or limbs; palpitations; and longings for noxious or unwholesome articles of food, or for what is not food. (See APPETITE — *Morbid*, and *CHLOROSIS*.)

3. This state of disease appears to be chiefly the result of diminished vital energy, produced by various mental and physical causes; in consequence of which state the food is not sufficiently elaborated and assimilated, the circulating fluid does not experience the requisite degree of change resulting from nervous influence, and the action of the viscera, and the secreting functions are imperfectly executed, whereby the whole mass of blood is impoverished or depraved, the manifestation of the nervous and muscular systems are feebly performed, and, ultimately, the whole of the structures more or less vitiated. (See BLOOD — *Alterations of*, in *Disease*.) Cachectic maladies are very frequently associated with, or preceded by, obstruction, or other disease of some important viscus. If the pulse does not exceed 80 or 84, particularly towards evening, we may conclude that the lungs are sound; and if the pulse be regular, and the sleep undisturbed, we may infer that the heart and its capsule are not, at least, seriously affected. The viscera most frequently diseased are the liver, mesenteric and lymphatic glands, the spleen, pancreas, kidneys, uterine organs, stomach and bowels; and the affection of these is sometimes a cause of, at other times an

attended on, or even consecutive of, the cachectic state; the vital endowment of the frame being the first to experience the morbid change. It would appear that the earliest manifestation of this change takes place in the ganglial system; the internal viscera and circulatory organs, whose functions are actuated by this system, becoming next disordered, generally in such a manner as to attract the attention of the observer to the nature and source of disturbance.

4. ii. The TREATMENT of cachexies chiefly consists of light nutritious food, taken in such quantity as the digestive organs can easily dispose of; healthy air, or change of air, with gentle and regular exercise, short of fatigue; of tonics combined with deobstruents and gentle aperients, in order permanently to excite the languid powers of life, and to promote the functions of the secreting organs; and of the use of chalybeate and deobstruent mineral waters, with frictions with stimulating liniments, and pleasant mental occupation. The sulphate of quinine, or the preparations of cinchona, particularly its compound tincture, with small doses of the bichloride of mercury; the various vegetable tonics, bitters and aromatics, with the mineral acids, especially the chloric acid; the preparations of iron; the chlorates of potash, soda, and lime; sarsaparilla, with guaiacum, &c.; the balsamic and terebinthinate substances; camphor, and the essential oils, and the preparations of iodine; are most serviceable in cachectic diseases, either exhibited singly, or combined with laxatives or purgatives so as to promote the secreting and excreting functions. As the various disorders of this description are often connected with obstructed function, or infarction, of some important viscus, it will frequently be requisite to exhibit at the same time, or in conjunction with some of the above remedies, small doses of blue pill, or of the hydrargyrum cum creta, or to combine them with rhubarb, aloes, or other purgatives, and often to add to them aromatics or warm gum resins. The object in these cases is to promote a regular action of the viscera, by increasing their vital energy; and this is better attained by adopting measures calculated to benefit the general health, and to increase the action of the stomach and bowels, than by the occasional use of active and debilitating cathartics; which, however, operate more efficiently and much more beneficially in those cases, when combined with bitters and tonics, — a fact long since insisted on by HOFFMANN, and others. (See also MERCURIAL CACHEXY, SCROFULA, and VENEREAL CACHEXY.)

CLASSIF. I. CLASS, V. ORDER (*Author*, see *Preface*.)

1. DEFIN. *General cachexy, with vitiated functions of the stomach and bowels, and a propensity to eat chalk, clay, or other dirty and unwholesome substances, generally affecting the aborigines of intropical countries, &c.*

VOL. I.

2. i. DESCRIPTION. — This disease is a complication of cachexy with anæmia and pica, or depraved appetite (see APPETITE — *Depraved*), at least in its advanced stages. It is very common amongst the natives of Africa, and the slaves in the West Indian colonies; and is attended with loss of appetite, continued pain of stomach, whiteness of tongue, difficulty of breathing upon the slightest exertion, drowsiness, inactivity, and general debility, despondency, with fondness of solitude, paleness of the face, lips, and palms of the hands, coldness, and often œdema of the extremities, glassy state of the *tunica adnata*, weakness and smallness of pulse, scanty, pale, or milky urine, whitish or clay-coloured stools, with other signs of depressed vital power and deficient assimilation. Owing to the depressed energies of the frame, and particularly of the digestive organs, a vitiated state of the juices of the stomach, with morbid acidity of the *prima via*, evidently prevails; occasioning sensations which probably excite the patient to have recourse to chalk, clay, or other absorbent matters to relieve them, and which occasion whatever vitiation of appetite may be additionally observed. This morbid condition appears, however, not to be limited to the stomach, but to be extended along the alimentary canal: the mucous surface of the bowels is in a state of morbid irritation, giving rise to offensive evacuations; the lacteal and mesenteric glands become irritated and obstructed, owing to the passage through them of unhealthy chyle and morbid secretions, and subsequently incapable of conveying sufficient nourishment into the circulation; the blood is thus rendered poor, pale, and in all respects such as is described in the article on the BLOOD (§ 34. *et seq.*); and the liver, pancreas, spleen, lungs, and heart, become pale, atrophied, and sometimes softened, from being deprived of the requisite nourishment, and supply of the circulating fluid. And at last the patient sinks from depression of the vital power and anæmia, presenting the following appearances on examination: —

3. The *stomach* is often flabby, softened, apparently distended, and pale. The liver is sometimes enlarged; occasionally atrophied, hardened, and generally very pale. The bile is usually watery, pale, or straw-coloured; the gall-bladder has contained biliary concretions in a few cases. The mesenteric glands are always enlarged and hardened. The mucous follicles of the intestines are often morbidly developed. The heart is soft and flabby; the blood in its cavities and large veins is watery and thin; and sometimes fibrinous concretions are found in these situations. Serous effusions, to a greater or less extent, are also frequently found in the thoracic and abdominal cavities.

4. ii. CAUSES. — This affection is very nearly allied to chlorosis: but whilst the latter affects females, and most commonly about the period of puberty, the former occurs in both sexes, and sometimes at as early an age as six or seven years. It is generally attributable to depressing or debilitating causes — mental or physical. The despondency and grief occasioned by separation from the place of nativity and friends, and by a state of bondage, often dispose to it; and thus it is not infrequently accompanied with nostalgia. The lax and weak habit of body, and the indolent disposition of the negro, seem also to favour the appear-

ance of the disease, particularly in those who have been badly nursed and neglected in early life. The chief exciting causes are, poor diet, hard labour, harsh treatment, exposure to cold and moisture, insufficient clothing, and venereal excesses early indulged in. The causes of the disease, the symptoms it presents in its progress, and the appearances observed after death, are altogether irrefragable evidence that it proceeds from great depression of the vital energies, especially of the digestive organs; occasioning, in its more advanced states, anæmia, imperfect nutrition, and vitiation of the fluids and soft solids of the frame.

5. iii. The TREATMENT is in no respects different from what has been recommended in general terms in respect of CACHEXIA and Depraved APPETITE (see these articles). Warm clothing, and a digestible nourishing diet, are indispensable to recovery; and to these should be added, regular but moderate exercise; bathing, followed by frictions of the surface; tonic, aromatic, and saline medicines; the use of the carbonates of the alkalies, combined with tonics and hot spices. Warm stimulating laxatives, such as the compound tinctures of rhubarb or aloes, or the bitter aperient tincture (F. 699.); the elixirs prescribed in the Appendix (F. 103—106.); the preparations of iron, cinchona, and myrrh; are severally of the greatest benefit, especially in conjunction with warmth, a residence in a warm dry situation, and sufficient nourishment. Care also ought to be taken to preclude any access to the substances for which the morbid propensity is entertained.

CÆCUM.—ITS DISEASES. 1. This viscus is not infrequently the seat of dangerous and fatal diseases, without any other part of the digestive tube being affected; and it is evidently concerned in the production of other disorders, in which it has usually been considered as merely accidentally to participate. If we consider its anatomical relations and functions in man and the lower animals, we shall be justified in viewing it as a distinct organ, performing offices modified in their nature from those of the rest of the alimentary tube. Notwithstanding this individuality, both its functions and its diseases have not generally attracted that degree of attention, nor received the investigation, they evidently deserve; and, hitherto, the latter have not even obtained a place in practical or systematic works. Some years ago, I took occasion to notice the importance of the offices and pathological states of this viscus, and detailed some cases in which it was remarkably diseased. Several facts illustrating the practical part of this subject have been recently accumulated, and some have since been observed by myself. From these sources, I shall arrange all that is known respecting the diseases of this organ, after having premised a few remarks on its functions.

2. The resemblance of the cæcum to the stomach in most of the gaminivorous, and particularly the ruminating animals, as well as its form and situation throughout all the higher classes of the animal kingdom, are circumstances showing that it is an important viscus, and one in which the last act of digestion is performed. M. VI-

RIDET appears to have been the first who entertained correct ideas of the actions of this viscus. "Sed de intestino cæco," he states, "quidquam dicere præstat, cum in quibusdam animalibus sit summè necessarium, nempe quibus et amplissimum, fors-anque vicem alterius ventriculi gerit; nam glandulis crassioribus donatur, quorum succus solutione heliotropii rubescit, et solutione sublimati albescit, suisque salibus acidis et volatilibus præditum est." (*De Prima Coctione*, p. 270.) This view has been recently confirmed by the able researches of TIEDEMANN and GMELIN, professors at Heidelberg. The situation of this organ, its capacity, its attachment to the parietes of the abdomen, and the circumstance of its contents being propelled in opposition to their gravity, are proofs of their longer retention than those of any other part of the digestive tube; and confirm the view that has been taken as to its being, in some respects, a reservoir, wherein is poured that portion of the materials remaining in the ilium, in order to undergo the latter stages of digestion, and the first of fæcation. Besides other proofs of these functions, it may be stated, that it is very abundantly supplied with large follicular glands, which, according to the experiments of TIEDEMANN and GMELIN, secrete an acid, albuminous, and solvent fluid, which mixes with, and promotes the digestion of, those portions of aliments which have withstood the actions of the stomach and small intestines, or been insufficiently changed by them. In order that this office may be the more completely performed, the anatomical relations of the cæcum admit of the remora, for a longer or shorter time, of the matters which pass into it; so that a last effort is here made to obtain the remaining nourishment from the ingesta: and thus it performs, if not the very last act of digestion, at least the last important part of it. But it also seems to fill an additional office, namely, that of secreting, chiefly from its numerous follicles, an unctuous or oily fluid for the protection of the surface of the large bowels from the irritating effect of the fæcal matters passing along them; and it is probable that the constituents both of this fluid, and of the other secretions poured out from its surface, consist of elements that require to be eliminated from the blood; so that, in addition to its other functions, it is also a de-purating organ.

3. The usual contents of the cæcum are of the consistence of a soft *bouillie*, or gruel, of a brownish yellow colour, and here first acquire their fæculent odour; which, according to TIEDEMANN and GMELIN, proceeds from the volatile oily substance secreted by its follicles. During the changes that are effected by the cæcum on its contents, an acid and hydro-sulphuretted hydrogen gas is disengaged. This gas seems to be generated only in small quantities during the healthy functions of the organ; but when its vital energies are diminished, and when, consequently, a greater remora than usual of its contents takes place, air is disengaged in much greater quantities, and sometimes to the extent of injuring its healthy tone. Whilst the cæcum reacts energetically on the distending power, this flatus, along with a portion of its contents, is thereby propelled along the colon: but on many occasions, and under particular circumstances, considerable opposition about

the right flexure of this bowel is offered to their transit; and hence, pain and uneasiness in this part of the colon, as well as in the cæcum, are complained of; giving rise to the idea of the existence of either hepatic or nephritic disease.

4. Under other circumstances of protracted disorder of the digestive organs, as when acidity is generated in the stomach and small intestines, and the food imperfectly digested; or when the ingesta are of a stimulating, irritating, or otherwise unwholesome kind; or when the secretions of the liver, pancreas, and mucous surface of the small intestines, are of a morbid or excoriating nature,—then the accumulation and remora of these matters in the cæcum are productive of disorder of its functions, of inflammation, and even of change of its structure.

1. DISORDERED FUNCTIONS OF THE CÆCUM.
CLASSIF. I. CLASS, I. ORDER (*Author*).

5. i. PATHOLOGY.—*A*. When the vital energies are weakened, and the alimentary canal debilitated, the cæcum often betrays greater disorder than any other part of the digestive system. Its situation and functions will, from what has already been stated, account for the frequency and importance of its diseases. In some cases, the irritation produced by morbid or accumulated matters in it is slight, and readily productive of sufficient reaction of its muscular coats to propel them along the colon. In other instances, the efforts made to accomplish this end, owing to the obstructions occasioned by the lodgment of flatus about the right flexure of the colon, or by irregular spasmodic contractions of this bowel, are ineffectual, and give rise to colicky pains. If the interruption is removed, disorder soon subsides; but if it continue for any considerable time, the more violent forms of colic or ileus supervene. When the internal surface of the cæcum is in an irritable state, disorders of this description are readily produced by the accumulation, even to a small extent, of the intestinal matters poured into it from the ileum, especially when they are of a more than usually stimulating kind, or if the secretions be morbid. In young, irritable, or nervous persons, and in those who partake of much acid or unripe fruit, or who neglect their bowels, particularly females who wear very close cinctures around the upper part of the abdomen, diseases affecting the alimentary canal, and, sympathetically, some other parts of the frame, not infrequently thus originate in this viscus. Accumulations, however, of alimentary and fæcal matters sometimes take place in it to a great extent, without producing much disorder, until the distension and irritation thereby occasioned give rise to disease of its internal surface, of its follicles, or its parietes generally. Persons advanced in life, of a phlegmatic temperament, or lax and torpid habit of body; those who take little exercise, or whose occupations are sedentary; and especially aged females; are very liable to be thus affected. During this state of infarction, the retained matters are more or less changed, partially decomposed, become acrid, excoriating, and a source of irritation both to the mucous surface itself, and to its follicles; which are thereby obstructed, and ultimately inflamed and ulcerated. In this way, most of the morbid states about to be described originate.

6. Several instances have been recorded by

the older writers, where the stones of fruits, biliary and intestinal concretions, and hardened fæcal matters lodged in the cæcum, have occasioned severe colic, and even fatal ileus. Some cases of this kind are referred to in Dr. MONRO's instructive work on Morbid Anatomy, as having occurred in his and his father's practice. In one of these, a concretion upwards of seven inches in circumference filled up this viscus. FONTANUS found an earthy concretion in it, as the only morbid appearance after death from ileus; and HELM, nearly three hundred cherry stones in the same situation, and in the ileum before it opens into the cæcum, in a fatal case of this disease. In some instances, accumulations of fæcal matters with great distension occur, without much suffering referrible immediately to the cæcum being experienced; the organs affected secondarily evincing the most marked disorder. This was shown by the case detailed by M. ODIER, of Geneva, of the celebrated M. DE SAUSSURE, in whom this viscus was very greatly dilated. When very much distended, it is generally diseased in other respects; its coats are more or less thickened, inflamed, and ulcerated, or its follicles enlarged. MONRO, NACQUART, and others, have adduced instances in which its engorgement and enlargement were accompanied with chronic inflammation and thickening. Mr. WILMOT relates a case in which it was dilated to the extent of containing a gallon, filled with fæcal matters and perforated by a circular ulceration. When the distension by accumulated matter is great, it may, from rising high in the abdomen, and pressing upon the nerves, vessels, and ducts in its vicinity, occasion numbness, and œlema of the right lower extremity, retraction of the testicle, and derangement of the urinary secretion; and thus be mistaken for disease of the kidney. M. DUCOS has detailed an instructive case of this kind; and two similar instances have been observed by me. In general, the seat of the tumour arising from collections of morbid matters in the cæcum, and the disorders connected with it, readily lead to the recognition of its nature, as in the case recorded by Dr. BARLOW. When, however, there is little or no tumour formed, and the symptoms are of a chronic and less violent kind, the cause of disorder may long exist in this situation, and escape detection. In a case of a young lady whom I attended with Mr. ANNESLEY, this part was considered as the seat of disorder, from its fulness and hardness upon an examination made when the patient was semi-recumbent, and the thigh slightly bent, and a treatment in accordance with this view strenuously insisted upon. She had been attended by several eminent physicians during the preceding three or four years, and very different opinions entertained of the nature of her ailments. After persistence in the treatment about to be recommended, an evacuation of hardened balls, containing indigestible substances which she had chewed many months previously, were evacuated, the fulness and hardness in the right iliac region disappeared, and the patient perfectly recovered. Two nearly similar cases to this were detailed by me in a work referred to below.

7. Substances incapable of digestion, either taken accidentally or from a depraved appetite, also frequently lodge in the cæcum, and remain

in it for a very long period, sometimes without producing much disorder, at other times occasioning the most violent effects. In other cases, in addition to various morbid matters, large balls of worms, both lumbrici and ascarides, collect in this viscus, and occasion much local irritation, or even inflammation of its inner surface, and constitutional disturbance. Mr. BLACKADDER has detailed some interesting instances of this occurrence. He found, in a patient who had complained of disorder of various organs, and of a gnawing soreness in the right iliac region, ragged ulceration of the inner surface of the cæcum, which contained an immense number of worms. The rest of the alimentary canal was sound.

8. *B.* When the cæcum is much enlarged, or otherwise diseased, it may also be displaced. Cases are recorded by SALZMANN and ANNESLEY, in which its attachment to the internal iliac muscle had yielded so far that it had passed over to the left side; and others, in which it had descended very low into the middle of the pelvis, and pressed upon the urinary bladder.

9. Not only may indigestible substances and morbid concretions sometimes lodge in the cæcum, producing much local irritation and general disturbance, but they may, when small, sometimes pass into the vermiform appendage, where they occasion, as will be shown in the sequel, the most dangerous effects. It does not, however, appear that the simple presence of any of these substances in this process is always followed by such results. Mr. BLACKADDER relates a case in which he found a small concretion in this part, and yet the patient had not complained of any symptom referrible to the right iliac region. I have treated, or been consulted respecting, four cases, in which foreign bodies and concretions were found in the appendix after death; and in all, the symptoms were those of the most violent peritonitis complicated with ileus, and terminating in sphacelation of this process itself. Two of these I attended with Mr. PAINTER, of Crawford-street, by whom the inspections were made; and who ascertained that the substance found in the appendix, in one case, consisted chiefly of cholesterine.

10. *ii.* SYMPTOMS.—The phenomena usually occasioned by fecal matters collected in the cæcum, and by distension, enlargement, or irritation of this viscus, will necessarily vary with the nature of the offending substances, the extent to which they may have accumulated, and the age, temperament, and habit of body of the patient. The disorders which result are, 1st, Local; 2d, Symptomatic, and 3d, Constitutional.—*a.* The local signs are more or less fulness, hardness, or distension in the right iliac region: sometimes, on examination carefully with the points of the fingers, the abdominal muscles being relaxed, a doughy hardness is felt. In other cases little or no pain, even upon a minute examination, is complained of; but occasionally, especially if the disorder be about inducing inflammation, both tenderness and pain either exist more or less constantly, or come on in paroxysms; and the patient generally reposes on the right side. When the bowels are constipated, and interruption of the passage of matters through the cæcum occurs, the paroxysms of pain are very acute, and sometimes attended by vomiting, and all the sym-

ptoms of the most severe colic, or even those of ileus. In such cases, upon examination, signs of obstruction either in the cæcum or in its vicinity are detected, unless general peritonitis may have come on; and then the origin of disease is very generally referred to the cæcal region, or the tenderness and pain are most acute in that situation.

11. *b.* The symptomatic disorders, when this viscus is much distended, either by fecal or other matters, or by flatus, or by both, as is most commonly the case, are, numbness of the right thigh, œdema of the right foot and ankle; sometimes retraction of the testicle, or frequent calls to empty the bladder, and sometimes hæmorrhoids; uneasiness or pain in the right iliac region, often extending to the hypochondrium; various dyspeptic symptoms, co-tive or irregular state of the bowels; occasionally diarrhœa, with scanty, offensive, and mucous stools; and, if irritation be excited in the mucous surface and follicles of the organ, the efforts made to evacuate the bowels are attended by severe tormina, and even by retching. I have seen several cases of varicose veins of the leg, or indolent ulcers, and a case of disease of the bones of the foot, the occurrence of which was evidently connected with great distension and accumulations in the cæcum; the symptoms of this disorder, with more or less tumefaction and hardness in the iliac region, having been found on examination. The justness of this view was fully shown by the success of the treatment, which was based upon it.

12. *c.* As long as the states of disorder have not advanced to inflammation or ulceration, the effects are often not very manifest upon the constitution. The countenance and skin, however, are pale and lax; the complexion is deficient of clearness, and, with the surface generally, often covered with an oily or dirty moisture; the perspiration is foetid, and the breath offensive; the soft solids lose their elasticity, and are slightly emaciated, the hips are usually pale, the tongue white or loaded at its centre and base, sometimes red at its point and edges; the pulse is weak, soft, or small, frequently slow, but easily accelerated; and, at an advanced stage, the symptoms more clearly manifest that the blood is imperfectly depurated, or that it is affected by the absorption of a portion of the excrementitious matters retained in the cæcum. In addition to these symptoms, general debility, and disinclination to any physical or mental exertion, are often complained of. The above states of disorder continue for a longer or shorter period; when at last the local irritation either produces increased action of the muscular coat of the cæcum, and ultimately the dislodgment of the offending matters, or gives rise to acute or chronic states of inflammation, and various consecutive organic changes. In some instances, the accumulation in this viscus, and the spasm of the adjoining parts, amount to complete obstruction of the passage through the alimentary canal, even without inflammation or any disorganisation of the cæcum itself having taken place; causing violent colic and ileus, as in the cases already noticed (§ 10.); the most marked symptoms during life being referrible to the superior portions of the tube, and the lesions after death being most remarkable in those parts, particularly about the

termination of the ilium, and the ilio-cæcal valve.

13. iii. TREATMENT. — The intentions in this state of disorder are very obvious; namely, 1st, to evacuate morbid collections; and, 2d, to prevent their re-accumulation, by preserving a regular tonic action of the viscus, and by strengthening the digestive organs generally. — *a.* The evacuation of the accumulated or retained matters is to be attempted by means appropriate to the circumstances of the case. If there exist irritability of stomach, or even any tendency to it, or to febrile action; or if there be any pain or soreness in the iliac region; full doses of calomel should be first exhibited, the enemata about to be suggested administered, and the liniments prescribed in the Appendix (F. 296. 311.) assiduously rubbed over the cæcal region, with the view of exciting the healthy action of the viscus. If, on the other hand, the stomach and bowels be torpid, and the former can retain purgative or cathartic medicines, they may be given, selecting those which are the least irritating in their effects. I have seen inattention to this caution, the most stimulating cathartics, having been exhibited, productive of the worst consequences; a state of disorder simply functional, or colic from distension and obstruction of the cæcum, being converted into either inflammation of the bowels or dangerous ileus. When, therefore, an irritable state of the stomach supervenes in our attempts to remove obstructions of this viscus, we should desist from the exhibition of purgatives, or even of aperients by the mouth, excepting full doses of calomel, or calomel combined with hyoscyamus or opium, and moderate doses of nitrate of potash, or carbonate of soda, or of both, which will generally be retained, and will allay the sickness and retchings. But we ought strenuously to persist in the administration of enemata — preferring those which are oleaginous, saponaceous, and solvent — and in the use of the liniments and frictions. The enemata should be always large, and injected by means of the valve-syringe now in use, so that they may reach the seat of obstruction. In obstinate cases, this object will be facilitated by placing the patient upon his knees and elbows during their administration, and elevating the pelvis as much as possible above the rest of the trunk. The practitioner should not be discouraged by the ineffectual administration of several injections, but repeat them according to circumstances, employing at the same time frictions over the abdomen with the liniments already advised. If flatulent distention of the abdomen be present, they will assist in removing it; but in such cases the terebinthinate enemata ought to be preferred. When we suspect the presence of worms, in addition to other morbid matters, aloes and the alkaline solutions, assafoetida, camphor, lime-water, &c. may be used in the injections. In the slighter and more usual cases, the aperients in common use, particularly castor oil, the compound decoction of aloes, the combination of the compound infusions of senna and of gentian, or the infusion of senna with decoction of cinchona, or the several formulæ of this description contained in the Appendix (F. 215. 266. 562. 575.), may be prescribed, as they may appear appropriate to the circumstances of the case.

14. *b.* Having apparently removed whatever

obstruction may have existed, — the cæcal region being soft and natural, and the actions of the bowels free, — the object is next to prevent the recurrence of disorder, and to strengthen the digestive organs, by vegetable tonics and bitters combined with aperients; by sulphate of quinine with aloes; by small doses of blue pill with the alkaline carbonates and other deobstruents, and given occasionally with the view of promoting and correcting the secretions; by the occasional use of the liniments above referred to, or by wearing a warm stimulating plaster (see F. 109. 115. 117.) over the right inferior regions of the abdomen. In every case, attention should be paid to the state of the digestive, assimilating, and secreting functions; regular evacuations of the bowels promoted, by the occasional use of enemata; and the diet strictly attended to.

II. INFLAMMATION OF THE CÆCUM. CLASSIV. III. CLASS, I. ORDER (*Author*).

15. Although inflammations of this viscus have been generally overlooked or confounded with those affecting either the colon, the small intestines, or the peritoneum, there are few diseases more defined in their character, or more distinctly limited in the great proportion of the instances of their occurrence, than they are. In respect of its seat, inflammation may affect chiefly the mucous surface, or the follicles, or all the coats of the organ more or less; or it may attack the vermiform appendix only, or the cellular tissue connecting the cæcum to the internal iliac muscle. As to the character of the inflammatory action, it may be sthenic and acute; or acute, asthenic, and spreading, as in dysentery and fever; it may also be more or less chronic. Cases of all these states of disease are to be found scattered through the works of modern medical authors, and most of them have come before me. The first case which attracted my attention to the importance of attending to the state of this viscus in various abdominal diseases, occurred in 1816, in a hot climate. The patient had the usual symptoms of inflammatory dysentery, with violent pain, and subsequently tumefaction in the cæcal region. The disease had been neglected in its early stages; and it was only shortly before the sudden subsidence of this tumour that I observed it. Upon straining at stool, a sensation of something having burst internally was felt; and very soon afterwards above a pint of purulent matter, mixed with a little blood, was discharged. Upon examination six hours after death, the cæcum was found ulcerated, discoloured, and nearly sphacelated, with an opening through the part attached to the abdominal parietes leading to the nearly empty sac of an abscess which had formed in the cellular tissue connecting this viscus to the side; the mucous membrane of the colon was inflamed in parts, and excoriated.

16. *i.* THE CAUSES of inflammations of the cæcum are chiefly the functional disorders already described. A morbid state of the abdominal secretions, and particularly an increased secretion of vitiated acrid bile; the irritation of foreign bodies, indigestible substances, and of worms; a strangulated hernia, or the pressure of an ill-constructed truss; the suppression of the hæmorrhoidal and menstrual discharges; and the presence of biliary or intestinal concretions, hardened faeces, or the stones of fruits, or their escape into the vermiform

appendage. Inflammatory irritation of the mucous membrane and follicles of the viscus is not infrequent after child-birth, and as an attendant upon some of the diseases which affect chiefly the bowels of females at this period. In connection with the accumulation and retention of morbid matters, it very often constitutes the earliest pathological state in dysentery and diarrhœa, and consequently then arises from the same causes that produce those diseases.

17. ii. SYMPTOMS. — *A. Of inflammation of the mucous surface of the cæcum.* These chiefly consist of an irregular, mucous, offensive, and sometimes slightly bloody appearance of the stools, with tenderness upon pressure or examination of the cæcal region. The evacuations are generally preceded by tormina or griping pain, extending from this part upwards to the right side, and down towards the pelvis. The tongue is slightly loaded or furred; and more or less symptomatic fever is present. This state of disorder is liable to lapse into a chronic form, and to continue for a long period; or it occurs primarily, from the functional disorders already described, and sometimes fluctuates as to the degree of severity. In the more slight or chronic states of inflammation of this surface, the patient often complains of little beyond irregularity of the bowels and colicky pains in the abdomen, with slight emaciation, and loss of the healthy complexion; till, at last, an acute attack of the disease supervenes, from the extension of the inflammatory action to the more exterior coats; or the chronic organic change has proceeded so far as to implicate adjoining parts, and to occasion a train of severe symptoms. In this manner, the more dangerous forms of dysentery not infrequently take place. During the earlier states of inflammation of the internal surface of the cæcum, ulceration may have commenced, or the follicles become diseased, and the coats successively perforated, until the peritoneal covering is attacked; when the inflammation assumes more serious features, owing both to its extension, and to the nature of the tissues which are now invaded by it. The perforation may, however, take place in that part of the parietes of the viscus where it is attached to the iliac muscle; and thus inflammation be extended to, and abscess form in, the cellular tissue exterior to it, and break either externally, or into the cæcum, or both; a sinuous communication being thus formed between the cavity of the organ and the surface of the body. In the manner now described, the more acute states of inflammation of the cæcum, and its connecting tissue, may arise; or these states may primarily affect the different structures composing its parietes, or may originate in its vermiform appendage.

18. *B. Acute inflammation of the coats of the cæcum* generally commences with violent pain in the right iliac region, frequently attended with a burning sensation, and most exquisite tenderness, particularly when the serous coat of the viscus is affected. It is accompanied with the most severe tormina, extending from the above region upwards to the right hypochondrium, across the abdomen, down into the pelvis, and along the thigh of that side. If the disease be attended by distension of, or faecal collections in, the cæcum, the testicle is retracted, and the thigh either very painful or numb. While the pain

occurs in paroxysms, and shoots in various directions throughout the abdominal cavity, it is constant and fixed in the situation of the cæcum. The regions of the abdomen, although sometimes distended and tense, bear examination, excepting in the cæcal region and its immediate vicinity, where the least pressure cannot be tolerated. The pain is usually increased when the body is erect; and the patient reclines on the right side, with the trunk slightly bent, and the thighs drawn upwards, so as to relax the parts in the vicinity of the disease. The bowels are generally torpid; but vomiting is not complained of, unless obstinate constipation exists, or drastic purgatives have been given early in the disease. The pulse is usually quicker than natural; but it is occasionally not much affected; and the temperature of the surface is increased. In some cases, the above constitute the chief symptoms; but in others much more disturbance ensues, particularly if the disease advances, or is neglected in its early stages, and the peritoneal surface of the cæcum is affected. When such is the case, the local symptoms increase in severity; the abdomen becomes more generally tense and painful, owing to the extension of the inflammation over the peritoneal covering of the viscus and the adjoining parts; and the symptoms of peritonitis, often attended by obstinate vomiting, supervene, with great frequency of pulse, and general fever. If the appendix participate in the disease, the symptoms are still more acute: general peritonitis is very quickly produced; adhesions are formed between it and the adjoining peritoneal surface; and the appendix soon sphacelates: a fatal result taking place, usually in a very short time. In other cases the disease assumes a somewhat less violent character, and terminates in suppuration, owing to the cellular tissue connecting the coats of the intestine to one another and to the abdominal parietes being chiefly affected. When this occurs, the issue is not so rapid as in the former instances, but is sometimes prolonged for a considerable period; and, in some cases, recovery is at last brought about. The foregoing history applies more strictly to inflammation originating in the cæcum; but when it commences in the appendix, or in the external connecting cellular tissue, the symptoms are often much modified.

19. *C. Inflammation of the appendix cæci* appears to be attended from its commencement with more acute symptoms than that of the cæcum itself. In four cases of this description which I have seen, this part was primarily and chiefly inflamed, owing to hard substances having escaped into it, and had occasioned general peritonitis, and gangrene of the appendix itself. In all of these, obstruction of the bowels, with obstinate retchings, was present at the time when I first saw them; and in the latter stages of the disease, vomiting was attended by violent tormina, and the discharge of matters evidently from the small intestines. Thus the symptoms of ileus were superadded to those of peritonitis. Upon dissection, the cæcum was found inflamed only in its peritoneal surface, in three of the cases; in the fourth, inflammation was observed also in its inner surface. In one, where the appendix contained a small biliary concretion, its extremity adhered to the surface of the cæcum after passing around a convolution of the ilium, which it had

evidently strangulated; but at the time of the inspection it was quite gangrenous on each side of the concretion. In another case, appearances of strangulation were manifested in a less satisfactory manner; the surrounding parts being so agglutinated by albuminous exudations, that their respective relations were not obvious. It does not appear, however, that inflammation originating in the appendix always arises from substances having escaped into it. M. LOUYER VILLERMAZ has detailed two cases of a similar state and termination of disease to the above; one occurring without any apparent cause, the other seemingly from the pressure of a bandage in hernia. In one, published by Mr. PARKINSON, ulceration and perforation of the appendix had taken place from the lodgment of a small portion of indurated faeces in it. A very interesting case, where violent abdominal symptoms were occasioned by a large lumbricus, which had passed into the cæcal appendage of a person otherwise diseased, is recorded by Mr. BLACKADDER. M. THIERY found this part engorged with faecal matters, and inflamed, in a fatal case of ileus; the cæcum being narrowed, but not otherwise diseased. HEISTER met with the appendix inflamed and ulcerated after death, with similar symptoms. AMYAND detected a small nail in this part after fatal ileus. MOREAU and KLOCKHOFF record instances of this disease produced by strangulation of the ilium by the cæcal appendage. Mr. WALDRON discovered a small concretion in it after fatal peritonitis; and MORGAGNI, VAN DOEVEREN, SANDIFORT, and several others, have detailed cases of both peritonitis and ileus, in which this part had adhered to adjoining parts; and, in some instances, a loop of intestine had been enclosed by it, and strictured. From the history of these, and other cases, which have occurred to me and several of my medical friends, it may be inferred, that inflammation affecting primarily the cæcal appendage is most frequently brought on by hard substances having escaped into it; and that the inflammation rapidly extends to the peritoneum; giving rise to the exudation of albuminous lymph, to adhesion of its opposite surfaces, and of the appendix to adjoining parts, and to gangrene of this process.

20. Very acute pain, tumefaction, and tenderness, are complained of upon the invasion of this form of the disease, first in the right iliac region, and subsequently more or less over the abdomen; with excruciating tormina, obstinate constipation of the bowels, a very frequent, small, or contracted pulse, heat of skin, dry tongue, great thirst, sometimes with numbness of the right leg, or pain shooting down the thigh, and retraction of the testicle. Vomiting comes on sooner or later, and is often, at one period or another, attended by the discharge of matters from the small intestines — at least in the cases which I have seen. The patient at last becomes restless, his countenance sunk, and a fatal termination takes place, generally from the third to the sixth day, preceded by the symptoms ushering in dissolution from intestinal peritonitis.

21. *D. Inflammation of the pericæcal tissue* is occasionally met with. Several interesting cases of it have been published by French writers, especially by MM. DUPUYTREN and MENIÈRE. Mr. COPELAND has detailed a case where a urinary calculus was extracted from an abscess which

opened externally, and communicated internally with the cavity of the cæcum. It is probable that the calculus, in passing along the ureter, had produced inflammation, extending to the cellular tissue exterior to the cæcum, and terminating in abscess, which had opened in both directions. In a case contained in Dr. JOHNSON'S Journal, and in another in which I was consulted, with Mr. FERGUSON, abscess had formed in the cellular tissue, external to the cæcum, had also burst into this viscus, and pointed externally; and a similar instance is recorded by M. DUPLAY. In all these a sinuous communication between the cavity of the intestine and external surface was formed. Several of the cases of inflammation of the cæcum and connecting tissue, detailed or referred to by M. MENIÈRE, terminated in suppuration, and opened either internally or in the right iliac fossa. In some of those published by M. DUPUYTREN, the purulent matter had infiltrated itself as high as the kidney, and as low in the pelvis as to collect between the rectum and bladder.

22. The *precursory symptoms* of this state of disease belong to pathological changes in the functions or coats of the cæcum itself, and are often similar to those already described as indicating acute or chronic inflammation of its mucous surface and follicles; the disease in such cases most probably arising from ulcerative perforation of the coats of the organ, or the extension of inflammation from its mucous surface. The patient frequently is first affected with either diarrhoea or constipation, or by both alternately, with colicky pains shooting in various directions, but generally radiating from the right iliac region; and he complains of pain or tenderness on pressure. To the above symptoms, others sooner or later are added, especially tumefaction, and constant pain in this part, and in the right iliac fossa, with anorexia, nausea, fever, and an irregular state of the bowels. As soon as suppuration commences, the disease presents the local and constitutional characters usually accompanying the formation of matter, with more or less tumour, which is generally situated deep in the iliac fossa.

23. Inflammation in this situation will, if recognised early and treated judiciously, terminate by resolution, in perhaps the majority of cases. But suppuration is almost as common a termination as resolution; and, when it takes place, the abscess formed most frequently opens internally. In several instances, peritonitis has supervened, either previously or subsequently to suppuration, but more usually the latter. The abscess may also open externally, as in the cases already referred to; but seldom without it having also previously established a communication with the cavity of the cæcum.

24. *iii. CHRONIC INFLAMMATION OF THE CÆCUM* generally comes on either primarily, slowly, and insidiously, or consecutively upon functional disorder of the viscus; and it may be long limited to the internal surface and follicles of the intestines, as noticed above (§ 17.). It more rarely remains after acute attacks. In the former mode of appearance, it often advances imperceptibly, until serious organic changes have taken place in the coats of the organ; the general health, although more or less affected, not being so far injured as to alarm the patient. In its progress, it sometimes presents occasional accessions of severity, and even assumes

a sub-acute form. In other cases, an acute attack is superinduced, which may terminate in peritonitis, or in suppuration, or even in gangrene. Chronic inflammation is the most common organic state of disease by which the cæcum is affected.

25. *A. Causes.*—This form of inflammation of the cæcum is, I believe, most frequent in females, probably owing to contingencies connected with the uterine functions and child-bearing, and to their modes of dress. It often occurs among them previously to menstruation, or soon after the climacteric epoch. Neglected functional disorder of the cæcum; the use of unripe or acerb fruits; sedentary occupations, or want of exercise; the depressing passions; previous disorder of the digestive organs, particularly costiveness, and habitually, or occasionally, deferring the earlier intimations to evacuate the bowels; suppression of accustomed discharges, especially the hæmorrhoidal, the menstrual, and lochial; the pressure of an ill-constructed bandage for hernia; blows or contusions on the cæcal region; and occasionally too violent exercise on foot or on horseback; are its most usual exciting causes.

26. *B. Symptoms.*—At first the general health and strength are not much injured; but the patient loses his healthy appearance and activity. He complains of colicky pains occurring occasionally, or even periodically, in the right iliac region, shooting through the abdomen, and recurring soon after a meal. The appetite is not materially affected, and flatulence is the most constant gastric symptom. The tongue is generally red at its point and edges, and loaded at its root; sickness and vomiting are not present; the pulse is often little affected, or it is quick and small; the patient lies on the right side, with the body bent and the thighs drawn up, and feels pain or uneasiness in the iliac region on turning to the left side, which is increased by continuing the position. The alvine evacuations are irregular and offensive, being at one time frequent, at another retained, generally muco-fœculent, fluid, preceded by colic or slight tormina, and affording little relief. The abdomen, on examination, presents little remarkable, until we reach the cæcal region, where pressure occasions uneasiness, and a deeply seated fulness and hardness are usually detected. If much fulness or distension be present, the urine is generally voided frequently, and slight pain or numbness of the right thigh, with œdema of the right ankle, is often felt. If the disease go on to ulceration, blood will appear in the stools, which will also be of a more or less dark colour. Such are the usual symptoms, until some one of the acute states of the disease supervenes, when their attendant phenomena will indicate the change.

27. *C. The chronic state of the disease may give rise to very great thickening of the parietes of the cæcum, either with or without dilatation of its cavity, and ulcerations in its internal surface.* FABRICIUS HILDANUS describes a case of this kind as one of cancerous ulceration; but it seems rather to have been chronic inflammation, with thickening and ulceration. Dr. BEZELY has detailed an interesting case very nearly of this description, wherein these changes were very remarkable. The patient complained of colic, constipation, flatulence, mucus bloody stools, and of a large tumour in the iliac region, which was

mistaken for aneurism of the iliac artery. On inspection, *post mortem*, the coats of the cæcum were found above an inch in thickness, scirrhous, inflamed, ulcerated, perforated, and its cavity enlarged. When the disease has gone on to thickening, as indicated by the obscure hardness, and tumour, uneasiness, &c., in the iliac region, particularly if it be attended with ulceration, as may be inferred from the presence of small quantities of blood or pus mixed in fluid, or but little consistent, muco-fœculent and offensive stools, amendment is procured with great difficulty, under the most favourable circumstances; but it should not be despaired of, although it may be long in appearing. I have met with severe cases, obviously of this description, where medical treatment was persisted in for many months, and one or two for some years, yet ultimately the health was re-established. In a case recorded by M. EMERY, the cæcum was remarkably constricted, and the appendix filled with faeces. The patient died of ileus.

28. *iv. COMPLICATIONS.*—Inflammations of the cæcum, particularly of its internal surface, and in their sub-acute and chronic forms, with morbid enlargement and fungous ulceration of its follicles, are very frequently associated with dysentery and fever, in both temperate and warm climates. Inflammation of its external connecting tissue is much less common in these complications. I ascertained the fact of the intimate connection of inflammations of the cæcum, with *dysentery*, in 1816, my attention having been first directed to it by the case already alluded to (§ 15.). Indeed, they generally constitute the original disease in dysentery; the irritative state of inflammation of the mucous surface and follicles of this viscus, together with the acrid secretions and other matters retained in it, producing an excoriating state of the discharges, whereby the cæcum itself is first affected, and subsequently those parts of the colon and rectum where they are the longest retained; an opposite morbid relation, however, obtains in respect of its complications with fevers, particularly those of a typhoid nature; for, while in dysentery it is frequently the primary affection, in fevers it is commonly a consecutive lesion arising from the morbid states of the secretions and matters, either retained in or passing through it, and from the disposition to change possessed by the mucous tissues and follicles during these diseases, particularly those of an asthenic character. It should not, however, be overlooked, that lesions of the cæcum may also arise in the course of dysentery, owing to similar states of the secretions and mucous surface of the intestines as are present in fevers; and that the cæcal disease will very generally escape detection during life, particularly in fevers, unless the attention of the practitioner is alive to its occurrence. In every case, therefore, should the region of this viscus be attentively examined; and, if symptoms indicating an affection of it be present, the means of cure should be directed accordingly.

29. *v. LACERATION, or RUPTURE of the cæcum* occurs in rare cases, either in consequence of previous disease and infarction of its cavity, or of external injury. Some instances of this occurrence are to be found in early volumes of the *Philosophical Transactions*, and in the *Transactions of foreign medical societies.* SOMMERING, in his notes to the translation of Dr. BAILLIE'S

Morbid Anatomy, mentions a case wherein it was produced by vomiting, which may have arisen from accumulation of morbid matters in the cæcum, with obstruction of its canal, and ulceration of its internal surface. Mr. SPEER and Mr. SHEWARD record instances of its rupture from contusion,—an event which is very likely to occur when an injury is sustained over it during distension of its cavity, from whatever cause. The consequence of its laceration generally is rapidly developed, and speedily fatal, peritonitis. *Introsusceptions* of this part, itself having passed into the colon, or portions of bowel having passed into it, are not infrequent, particularly in young subjects; but they require no particular notice, farther than as a cause of *ileus*, inflammation of *intestines*, &c. Cauliform, and other fungous excrescences, may occur in the cæcum, as well as the other morbid changes described in the article DIGESTIVE CANAL.

30. vi. The PROGNOSIS in disease of the cæcum is very different in each of its forms.—*a.* When the *internal surface* is chiefly affected, recovery will take place in most of the cases, unless ulceration has commenced; and even then a favourable issue will sometimes follow judicious medical treatment and regimen. *b.* In the *acute states* of inflammation affecting the more external coats of the viscus, the prognosis is upon the whole unfavourable, at least it should be stated as such to the friends of the patient; and in every case it should be given with caution. *c.* If we suspect, from the severity of the symptoms, or from the rapid extension of inflammation from the caecal region over the abdomen, that the *appendix is inflamed*, it is still more unfavourable; if, in addition to this circumstance, the retching be frequent, and more particularly if the matters ejected appear as having come from the small intestines, we may infer, not only that the cæcum or its appendage is most acutely inflamed, but also that either its canal is obstructed, or some adjoining part of the tube is strangulated;—in either case the prognosis is most unfavourable. The subsequent appearance of the symptoms usually indicating gangrene of the intestines leaves no hope, and is soon followed by dissolution. *d.* When considerable tumour, seated in the iliac fossa, and the signs of inflammation of the *pericecal tissues*, are present (§ 22.), a favourable opinion of the issue may be entertained, if active treatment have been employed early in the disease, and the patient's constitution be not in fault. But in very many such cases, the general health has been much impaired previously to this disease, and has even predisposed to the attack. In such cases, as well as when evidence of the formation of *abscess* is observed, a very unfavourable, or at least a very cautious, prognosis ought to be given. *e.* In the *chronic states* of the disease any opinion should be offered with much reservation. If the disease have come on slowly, continued long, and the stools present the appearances indicating ulceration (§ 26.), an unfavourable state of disease exists; thickening of the coats of the viscus merely (§ 27.) is more favourable, but is not readily removed. *f.* The *complications* of this disease (§ 28.), particularly with typhoid fever, are attended by considerable danger. The association of it with dysentery is productive of the worst forms of that disease, as well as its complication with fever, of its most

dangerous states; and causes the former to assume a chronic and obstinate form. *g.* *Laceration*, or rupture of the coats of the cæcum, is generally fatal in its results.

31. vii. TREATMENT.—*A.* Inflammation of the *internal surface* of the cæcum, and the *chronic states* of the disease (§ 17. 24.), require the application of a number of leeches either near the iliac region, or on the inside of the right thigh, and a repetition of them according to the circumstances of the case. In robust or plethoric persons, general depletion may precede the local. After the leeches are removed, fomentations and a succession of poultices will be found serviceable; after which, a full dose of calomel with James's powder, and, a few hours subsequently, a mild aperient medicine, should be exhibited, and an aperient action promoted by the administration, and frequent repetition, of demulcent, oleaginous, or saponaceous enemata (§ 13.). Drastic purgatives are seldom more efficacious than those of a milder kind, but are often attended with risk. I have generally found the infusion of rhubarb, with tartrate of potash, and the electuaries prescribed in the *Appendix* (F. 82. 89. 98.), most serviceable. In the majority of cases, the above means will remove all ailment. The treatment in other respects should be the same as is recommended in chronic *Diarrhœa* and in *Dysentery*. If functional disorder remain after the more inflammatory symptoms have subsided, a blister may be applied, or a deobstruent liniment (§ 13.) rubbed over the caecal region night and morning; or a rubefacient and deobstruent plaster (§ 14.), worn for some months in this situation.

32. B. In the *more acute states* of the disease, general *blood-letting*, repeated according to the circumstances of the case, or followed by local depletions, and the same treatment subsequently as described above (§ 31.) must be early and decidedly employed. If there be vomiting, or retchings upon taking substances into the stomach, a large dose of calomel,—generally from 10 to 20 grains given either alone or with one or two grains of opium,—will allay this disorder. If the symptoms still continue, or if they be but slightly mitigated, blood-letting, general and local, followed by fomentations, poultices, and oleaginous enemata, having been carried as far as may be deemed prudent, the turpentine embrocation (flannel cloths wrung dry out of very hot water, and immediately soaked with spirits of turpentine), should be applied over the abdomen, and retained there as long as it can be borne by the patient. If the termina be severe, or if peritonitis have supervened, this embrocation is, after depletions have been practised, the most efficacious means we possess. In a case of this disease, which had become complicated with peritonitis, in a member of the family of a medical friend, this means gave almost instant relief, after other measures had been carried to the utmost limits, and the patient soon afterwards recovered. In another instance of extreme danger similarly complicated, which very recently occurred, the repetition of this treatment removed all complaint, although resorted to in despair of success from it.

33. C. I have stated that *inflammation* of the *appendix cæci*, particularly when occasioned by hard bodies having passed into it, often does not extend to the cæcum itself, or, at most, only to

its peritoneal coat, in common with the adjoining portions of this surface; but that the supervation, the extension, and fatal termination of peritonitis in such cases are most rapid and dangerous, the appendix itself generally soon becoming gangrenous. It therefore behoves the practitioner to have recourse to the most decided measures, when he finds the symptoms of peritonitis originate in the cæcal region, and when retchings come on. Vascular depletion, and all the remedies already noticed, must be energetically and early employed; but premature attempts should not be made to evacuate the bowels, otherwise their action will be inverted, and decided symptoms of ileus will be produced. Fomentations should follow the leeches; and afterwards hot poultices should follow; which in their turn ought to give place to the terebinthinate embrocation, if requisite. A large dose of calomel and opium should, however, be given after the first full blood-letting; this will generally be retained, even in the worst cases; and it ought to be repeated according to circumstances, without fear of affecting the system by it, — an effect which it is even very desirable to produce. Little other medicine need be exhibited by the mouth, excepting draughts with nitrate of potash, or carbonate of soda, or both, with agreeable demulcents and emollients, if the stomach will retain them. But the assiduous administration of *enemata* must not be neglected. It is entirely by their agency in this state of disease, that the bowels are to be evacuated, when it is judged prudent to fulfil this intention, which should seldom be omitted as far as they are calculated to accomplish it; more especially after depletions have been practised. The enemata prescribed in the *Appendix* (F. 130—151.), as they may appear suited to particular cases, may be employed. Pain, tormina, nausea, or vomiting, having been relieved, gentle cooling aperients, and in the interval diaphoretic medicines, may be exhibited by the mouth. Warm baths are seldom of much use in this malady; but when they will not interfere with the treatment prescribed, they may be tried, particularly in the more advanced periods. After the disease has been removed, and merely functional disorder remains, the measures already advised may be put in practice.

34. D. The treatment now described is also applicable to the early stages of inflammation affecting the *pericæcal tissues*. If suppuration takes place, the treatment recommended for *Abscess* must be resorted to; taking care to support the energies of life under it, particularly when the constitution or general health is in fault. If we suspect either the existence of *ulceration* or of *thickening* of the coats of the viscus (§ 27.), the assiduous employment of the liniments noticed above; of gentle aperients and deobstruents, particularly the infusion of rhubarb with soda or potash; of electuaries, with sulphur, bi-tartrate of potash and soda, or the bi-borate of soda; small doses of blue pill or hydr. cum creta, with ipecacuanha, hyoscyanus, and camphor; repeated blistering, and subsequently the deobstruent plasters; the frequent use of large oleaginous, saponaceous, and demulcent enemata, with the treatment recommended in chronic *dysentery*; are the measures most to be depended upon; with strict attention to diet, which should be chiefly farinaceous, to the state of the digestive

organs generally, and to the secretions and excretions.

35. E. The complication of the disease with *dysentery* requires, in addition to the measures used for that disease, the application of leeches near the right iliac region, and the other external measures already noticed, with rhubarb aperients, combined with camphor, narcotics, and ipecacuanha; laxatives, with demulcents and anodynes; the frequent administration of oleaginous and emollient enemata; and the usual means of correcting the secretions, and diluting and carrying off the acid and excoriating fluids, and læcal matters in the intestinal canal. (See *DYSENTERY — its Treatment*.) A similar treatment to the above is necessary when the disease occurs in the progress of *fever*. Depletions, however, are generally not so well borne in this complication as in the former, and should therefore be carried to a less extent; but all the external remedies, and the use of laxatives, particularly those imparting a tonic effect to the intestinal mucous surface, should be often employed. Camphor, with hydrarg. cum creta and opium, or with ipecacuanha and rhubarb, terebinthinate injections, or even a terebinthinate draught in the worst cases, have proved most serviceable in this state of complication, in my practice. During recovery, the occasional use of the liniments and plasters above referred to, attention to the secreting and digestive functions, particularly to the state of the bowels, which should be occasionally assisted by emollient and laxative injections; and a regulated diet, easy travelling, change of air and of scene; are the chief measures requiring attention. (See the treatment of *FEVER*.)

CANCER. SYN. *Scirrhus*, *Carcinus*, *Schirrus* — *Cancer*, *Carcinoma*, *Auct. Vâr. Cancer*, *Fr. Das Krebsgeschwür*, *Ger. Scirro*, *Canchero*, *Canero*, *Ital.*

CLASSIF. 4. *Class*, Local Diseases; 6. *Order*, Tumours (*Cullen*). 3. *Class*, Sanguineous Diseases; 4. *Order*, Cachexies (*Good*). IV. CLASS, IV. ORDER (*Author*, see *Preface*.)

1. DEFIN. A disease often arising from hereditary predisposition, in the middle or advanced

periods of life; commencing with a local hardness, which subsequently softens in its centre, infects the adjoining parts, and ultimately contaminates the frame.

2. Cancer consists of two states or stages: the first, in which it presents the appearances usually denominated *scirrhus*; the second, in which it softens, ulcerates, &c., and degenerates into true cancer, or carcinoma. I shall describe each of these successively.

3. 1. SCIRRHUS STAGE.—*Occult cancer.* It commences with a tumour, a limited local hardness; is usually single; is very rarely, at its commencement, detected in different parts at once; and is not surrounded by a cyst. Several authors have stated the occurrence of a cyst; but OTTO more accurately excludes it from this structure. It is of importance to attend to the appearances of the disease at its commencement, as serving to indicate its nature. It is distinguished, at this period, by hardness, coldness, whiteness or paleness, insensibility, and deficiency of red blood vessels;—a state indicating the low grade of vital endowment of the part.

4. The scirrhous structure, when fully developed, consists of a firm, hard, rugged, incompressible, and unequal mass, the limits of which are not distinctly defined. Its colour is generally of a light grey, and when cut into thin slices, it is semi-transparent. Upon close inspection, it is found to consist of two distinct substances;—the one hard, fibrous, and organised; the other soft, and apparently inorganic. The former composes the chief part of the diseased mass, and consists of septa, which are opaque, of a paler colour than the soft part, unequal in their length, breadth, and thickness, disposed in various directions; sometimes forming a nearly solid mass; in other instances, a number of cells or irregular cavities, which contain the soft part. This latter is sometimes semi-transparent, of a bluish colour, and of the consistence of softened glue; at other times more opaque, softer, somewhat oleaginous, and like cream in colour and consistence.

5. The fibrous structure seems to be the cellular, or proper tissue of the part, in a state of induration and hypertrophy; assuming, in consequence of its increased density and bulk, an appearance similar to the fibrous or fibro-cartilaginous structure; whilst the softer portion, contained in the meshes and cells of the former, appears to be merely a morbid secretion poured out by the vessels nourishing the organised fibrous tissue, and is probably the exhalation of the part, either secreted in a modified state, or accumulated and changed by the disease of its containing structure. If this view be correct, the former, or organised part, may be considered as chiefly resulting from an altered state of nutrition in the seat of disease; whilst the latter, or inorganised portion, may be viewed as proceeding from a morbid secretion,—the diseased structure thus being a product of a disordered state of both the nutritive and secreting functions, most probably in consequence of alteration of the vital influence exerted by the ganglial nerves on the capillaries of the part.

6. The proportion of each of those two substances, and the modes of their distribution, vary very considerably in different scirrhous masses. This diversity seems to be owing to the different tissues in which they are developed, and to the

modifications arising from temperament, local irritation, and various concurrent circumstances to which the patient may have been exposed. It has been attempted by Mr. ABERNETHY to arrange these varieties of scirrhus into species, and to designate them according to the natural structures which they most resemble. Thus he divides them into Mammary, Pancreatic, Tuberculous, &c.; but these different states of structure glide so insensibly into each other, and are so perfectly similar as respects their origin and consequences, that little practical advantage is derived from thus distinguishing them.

7. In some scirrhous tumours, the fibrous part of their structure is both most conspicuous and abundant, and is condensed into a solid mass, having the appearance of a centre or nucleus, whence radiate numerous septa in every direction. This is the most common appearance of the disease. In other instances, the tumour forms an uniformly hard mass, of an irregular shape, and of no very defined structure. In some cases, the organised part approaches more nearly to the cellular structure, its cells being filled with a soft matter which may be pressed out. Occasionally, cysts are formed within the tumour, of various sizes, containing a reddish, reddish brown, or a chocolate-coloured fluid. These cysts are lined by a smooth membrane, from which a fungous tumour sometimes sprouts out. In some instances, portions of the scirrhous mass are converted into a hard substance resembling cartilage, in which bony or calcareous depositions are occasionally found. When the scirrhous structure is formed in the substance of a gland, its limits cannot generally be accurately determined, the two structures apparently being inseparably connected. In some cases, the scirrhous tumour condenses the cellular tissue surrounding it, and hence it acquires a somewhat sacculated appearance. (WARDROP.)

8. At the commencement of scirrhous disease, the structure of the tissue or organ in which it is seated preserves for some time its aspect and colour, being changed merely in volume and density: sometimes, however, its volume is but little augmented, whilst its density is very much increased. As the disease advances, the proper tissue of the organ becomes more obscure, and verges nearer to that already described.

9. M. HECUT, of Strasbourg, analysed a portion of fully developed scirrhus of the mamma, and found 72 grains composed of 2 grains of albumen, 20 of gelatine, 20 of fibrine, 10 of a fluid fatty matter, and 20 of water and loss. He likewise analysed, by a similar process, 72 grains of scirrhous uterus, and found it to consist of 15 grains of gelatine, 10 of fibrine, 10 of oily or fatty matter, and 35 of water and loss. (LOBSTEIN, *Anat. Path.* t. i. p. 403.)

10. Scirrhous tumours do not always remain in the state now described; and the period during which they thus continue is not determinate. When once they commence, they seldom retrograde, and the part affected never is restored to its healthy state. It is chiefly in this respect that the early stages of scirrhus differ from simple induration proceeding from chronic inflammation. Scirrhus may remain nearly stationary for several years, occasioning but little constitutional disturbance; but generally an important

change takes place in its structure, and the disease afterwards makes rapid progress.

11. II. CARCINOMATOUS, OR CANCEROUS STAGE. — *Open or ulcerated cancer.* After a time, portions of the scirrhus mass begin to soften, and pass into a state of unhealthy suppuration and ulceration, — unhealthy as respects the characters and progress of these processes, and their contaminating influence upon the whole frame. The soft or inorganic substance resolves itself into a thin ichorous matter, very different from pus; and disorganisation commences, generally about the centre of the mass, and extending towards that part of it which is nearest either the surface of the body or any of the natural openings. When this process commences, it is in that state which has been denominated CARCINOMA, OR CANCER. When this change takes place, the diseased mass seldom increases much in bulk, but is destroyed by an ulcerative process. The disease now makes rapid progress, owing to the contamination of the adjoining structures by the morbid matter secreted by the ulcerating part, a portion of which matter is evidently absorbed, irritating the lymphatic glands, and vitiating the whole frame. In consequence of this infection, the powers of life sink, the soft solids become cachectic, and the progress of the local affection accelerated. At last the patient sinks from the contamination of the circulating fluids, and the different textures of the body; the blood being diminished in quantity, as well as otherwise altered.

12. When the skin covering a scirrhus tumour ulcerates, a fungus of a cauliflower appearance, and hard gristly structure, sometimes proceeds from the surface of the mass. In some cases, ulceration destroys both the fungus and the primary tumour. It has been observed by Sir E. HOME, that some cancerous sores have suddenly changed from a painful and malignant character, to a more healthy aspect at some part, and even have begun to cicatrize. This apparent amendment is never permanent, for, sooner or later, the ulcerative process is renewed, and the disease pursues its usual course. Dr. PARR (*Dict. vol. i.*) states, that he has seen several cases thus terminate spontaneously; but the patients were all soon afterwards cut off by internal disease; probably consisting of the internal development, or metastasis of the malady, cases of which occurrence are not infrequent. (See *Journ. Hebdom. t. i. p. 323.* for a case wherein internal cancer appeared after the removal of the external disease by compression.)

13. Cancerous tumours generally contaminate the glands in the vicinity, particularly after ulceration has commenced. But these glands are seldom primarily affected. Mr. WARDROP states, in his excellent description of this disease, that he has only met with two cases of primary affection of the lymphatic glands. Besides these glands, various other organs and parts, sometimes far removed from the seat of the primary disease, become secondarily affected. This is most probably occasioned by contamination of the frame, from absorption of the morbid matter of the disease. Sometimes the existence of cancer in distant organs is not successive or secondary, but seemingly coeval. In this case the cause must be looked for in the originally morbid state of the system. Indeed, this state always obtains, to a certain extent; the disease being strictly constitutional even

in its origin; the consecutive contamination, arising from the absorption of morbid matter from the primary tumour, merely augmenting the original vice, and accelerating its noxious effects.

14. Scirrhus-cancer most commonly originates in glands whose functions have been interrupted, or that have never performed the offices intended for them; or it affects parts which have been previously diseased, or have received at some period an external injury. Thus it attacks the mammae, the uterus, the ovaria, the testes, the thyroid glands. It also very frequently commences in the tegumental, and the digestive, and urogenital mucous surfaces; more particularly in the skin of the face; in the mucous membrane of the nose, lips, mouth, pharynx, and œsophagus; in the stomach, especially the pylorus and cardia; in the intestinal canal, the ilio-cæcal valve, rectum, and anus, and in the urinary bladder. The viscera which are secondarily affected, are commonly the lungs, bronchial glands, the liver, the omentum, the mesentery, the serous membranes, the spleen, the pancreas, the brain, the medulla of the bones, and the skin. Several of these, particularly the liver, pancreas, mesentery, brain, &c. may also be primarily or coevally affected with other parts. Scirrhus affects the skin in two forms; — the one is that of wart, the other that of tubercle — the former being primary, the latter secondary.

15. III. DIAGNOSIS.—It is of great importance to be able to distinguish between this disease and various others, for which it is liable to be mistaken. For instance, the simple induration proceeding from chronic inflammation has, in several instances which have come to my knowledge, been mistaken for scirrhus. This mistake not infrequently occurs in respect of induration of the neck of the uterus.

16. A. In *simple induration*, the part affected is redder, more injected, retains more of its original structure, is less indurated, and less lobulated, than scirrhus. The parts also surrounding the indurated portion are frequently slightly infiltrated with serum. Induration, the result of inflammatory action, admits of resolution, and entirely disappears, sometimes in consequence of a natural flux or evacuation, of active exercise, the return of accustomed discharges, or pregnancy. Thus the menstrual flux sometimes dissipates inflammatory induration of the mammae, or of the neck of the uterus.

17. B. The *fibrous production* generally appears in the form of a rounded body, implanted, but isolated, in the proper structure of the organ, and adhering to it merely by means of laminated tissue. Upon dividing the structure, it grates under the scalpel; and it sometimes presents dilated vessels, which are never observed in scirrhus masses; moreover, it occasions little or no pain, and never passes into the cancerous state.

18. C. Compared with *tubercular* or *lardaceous* productions, scirrhus-cancer offers remarkable differences: — 1st, This latter is never found isolated in the cellular tissue, or in the parenchyma of organs, in the form of granulations, or of small rounded tumours, as the tubercular formations are; nor in largely diffused masses, as the lardaceous substance: 2d, It is never enclosed in a cyst: 3d, It does not greatly increase the volume of the part it affects; sometimes the part is even

diminished, but much more dense: 4th, It is not susceptible of the same kind of softening as the tubercular and lardaceous productions; but rather of a peculiar rarefaction, passing into a peculiar form of fungus, followed by the development of blood-vessels: 5th, Its vital properties are excited, and its sensibility becomes exalted, as the disease advances,—circumstances which are never observed in connection with these productions.

19. *D. Cancerous ulceration* is characterised by a jagged, thick, soft edge, which is turned outwards. The surface of the ulcer is greyish, or greyish brown, sometimes livid brown, elevated into loose, fungous vegetations, discharging a fetid, corroding *sanies* or *ichor*, and bleeding slightly upon irritation. —*a. Chronic inflammatory ulcers* differ from the former in the absence of a fetid corroding ichor; in the hardness of their margin, which turns inwards; and in the reddish and more healthy appearance of their bottoms, which in cancer is colourless, or a livid brown, hard, irregular, fungous, sometimes with cauliflower excrescences, and extremely offensive. —*b. Local tumours* sometimes appear, particularly on the tongue, originating in irritation, and exasperated by the continuance of this cause. These usually commence with a small pimple or wart, becoming more and more hard and irritable as they increase, until they assume a scirrhous-like induration. They seldom endanger the constitution, yet appear sometimes to assume a malignant character. (Mr. EARLE, in *Trans. of Med. Chir. Soc. vol. xii. art. 22.*)

20. *E.* As soon as the *carcinomatous change* takes place in the scirrhous mass, the disease involves adjoining parts, and the system generally. The local suffering is more fully developed, and the vital actions of the part are changed greatly from the healthy course. The sensibility is morbidly augmented in short paroxysms; the pain being violent, and what is usually called *lancinating* or stinging during the exacerbations, but often slight, or almost altogether absent in the intervals. If the surface be exposed, the pain is burning, and the part is always sore. As the disease advances, and particularly as the ulceration proceeds, the paroxysms of lancinating and burning pains increase in violence, and the remissions become more imperfect, and of shorter duration. The *cancerous sanies* is generally very fluid; but its appearance varies with the treatment, the situation of the disease, and with the diet of the patient. It is generally of a greyish white, or reddish grey; it slightly effervesces with sulphuric acid, and turns syrup of violets to green.

21. *F.* The *extension* and *contamination* of the system characterising cancerous ulceration appear to be owing, 1st, to the corroding influence of the secretion on the parts with which it is in contact; 2d, to the absorption of a portion of the morbid secretion by the lymphatic vessels: this is evinced by the swelling and affection of the glands in the vicinity of the primary disease. But the affection of the glands may not be altogether owing to the absorption of the morbid matter, but partly to the irritation of the lymphatic vessels occasioned by the disease of the part in which they originate: and, 3d, to the absorbing function of the veins, according to the researches of MAYER, MAGENDIE, TIEDEMANN, GMELIN, &c. These different sources of contamination seem more than sufficient

to account for the general cancerous cachexia characterising the advanced stages of the disease.

22. *G.* The characters of this *cancerous cachexia* are, emaciation; softness and flaccidity of the soft solids; œdema of the extremities; hectic fever; a peculiar change of the complexion and colour of the whole surface of the body, which become of a pale leaden, or pale straw colour, or waxy hue; and general depravation of the functions. This state of cachexia increases with the progress of the disease, and augments at the same time the primary local change. It is rapidly developed and increased when the scirrhous mass ulcerates, when also carcinomatous tumours frequently manifest themselves in various parts of the body. Ultimately the circulating fluid is deficient in quantity, and is poor and morbid; and the vital cohesion of the soft solids, and even of the bones, is diminished.

23. *IV. CAUSES.*—*A. Predisposing.*—Scirrhous, like scrofula, is undoubtedly an hereditary malady. Instances are numerous of several individuals in the same family having been affected by it. It is almost altogether confined to persons advanced in life. Cases of the disease are very rare before the age of thirty. Sir A. COOPER met with it only twice previously to this age. Mr. WARDROP has seen one instance of it in the skin of a girl of twelve years. Females, owing to the liability of their appropriate organs to be attacked, are more subject to it than males; especially those who have not borne children, the disease appearing in them upon the cessation of the catamenia. It seems commonly to result from an original or acquired diathesis, existing previously to the development of morbid structure, and very often connected with the lymphatic temperament. MM. BRESCHET and FERRUS found 23 instances of this temperament prominently marked, out of 44 cases of the disease. Anxiety and distress of mind, and all the depressing passions, are most disposing causes, particularly to cancer of the breast. An inactive state of the part for a considerable time previously; a poor, unwholesome diet; laborious and exhausting occupations, and an unhealthy locality; also dispose to it.

24. *B.* It is generally *excited* by blows and external injuries; by repeated or continued irritation; the abuse of spirituous liquors; and by low and poor diet. It is not liable to be propagated by contagion; the experiments of MM. ALIBERT, BIET, and DUPUYTREN, having shown that the matter discharged from a cancerous ulcer cannot produce the disease in another person. Although irritating agents of any description may give occasion to its appearance, yet there must have previously existed a cancerous diathesis, or constitutional disposition, in which it almost always originates.

25. *C.* The *proximate cause* of this dreadful disease is extremely obscure; and opinions respecting it have consequently been numerous. SCHLEFFER and GAMET consider it to be caused by a singular depravation of the nervous fluid. Dr. ADAMS and Dr. BARON impute it to the existence of an hydatiform body, which they call the *hydatis carcinomatosa*; and Mr. CARMICHAEL, to a body enjoying an independent state of existence developed in those parts of the frame, the vitality of which is enfeebled, and the organised matter of which begins to be decomposed. He supposes that, at first,

the constituent of cancer occupies but a minute spot, consists of a substance nearly similar to cartilage; and that it afterwards extends itself in the form of radiations, resembling ligaments formed by thickened cellular tissue. These opinions, which are not essentially different from each other, have been completely refuted by BURNS, CLERI, and HIMLY. According to M. BROUSSAIS, scirrho-cancer is the result of an inflammatory or sub-inflammatory state of the vessels (*Examen des Doctrines Méd.* t. i. prop. 93—95.); and the opinions of MM. BÉGIN, BRÉSCUET, and FERRUS (*Dict. de Méd.* t. iv. p. 133.), differ but little from that of M. BROUSSAIS. They impute the disease to irritation of an inflammatory nature, occasioning the secretion of a coagulable lymph that becomes condensed into a scirrhous substance, which may remain stationary for a longer or shorter period, but which sooner or later undergoes a secondary inflammatory process, and experiences softening and disorganisation, with various other changes, as these processes proceed. To this doctrine of the modern French pathologists it may be objected, that scirrhous furnishes no sign, local or general, of inflammation, and yet it goes on increasing; and if it can increase rapidly without inflammation, may it not also originate independently of this cause? Where, therefore, neither the local appearances, nor the usual consequences, nor the constitutional symptoms, of inflammation can be perceived, ought we to impute the disease to this state of vascular action? The inference is obvious; but it is only one of many arguments, which, if they were not superfluous, might be adduced against the doctrine.

26. According to M. ANDRAL, cancer is not a specific alteration, but a state of disease arising from lesions of nutrition and secretion, which have reached the period of their termination in ulceration; the ulcer thus arising, constantly increasing either in depth or extent of surface, without any disposition to cicatrization. Thus, M. ANDRAL considers cancer in a generic acceptance, and comprises under it the ulcerative process in various species of disease of a constitutional origin and malignant nature, which, although always considered as closely allied, in their origin, nature, and tendency, to scirrhous, have usually been viewed as distinct maladies. This opinion is more in accordance with the wide signification of the term *cancer*, in the writings of French pathologists, but is very deficient in precision and applicability; inasmuch as it embraces the advanced states only of several organic changes, which, in their earlier periods especially, are very distinct from one another—distinct in causes, origin, the structures they principally attack, and in their appearances and properties. I have, therefore, adopted the more accurate views of British pathologists respecting this disease, which I consider in relation to its predisposing and exciting causes, to the states of the system in which it occurs, to its local appearances, and constitutional effects, to the results of treatment, and to the ultimate changes produced in the blood, and in the various structures, as essentially depending upon a weakened and otherwise morbid state of the system generally; and arising from deprivation of the vital conditions of the part affected, whereby its nutrition, nervous sensibility, and secreting function, become specifically changed, and all the fluids and solids ultimately contaminated.

27. V. TREATMENT.—The conclusion now drawn respecting the nature and morbid relations of *scirrho-cancer* must render very apparent the futility of various measures which have been employed to remove it. Some writers have too exclusively viewed the disease as local; and thus, even in its advanced stages, resorted to most dangerous and painful operations to extirpate an evil, which, instead of being local, proceeds from the morbid state of the system generally, and which all depressing causes (the surgical operation itself being one) rapidly increase, disposing not only to its extension in its primary seat, but also to its appearance in new situations and more vital organs. The means of cure, therefore, should have especial reference to the state of the constitution favouring its development and progress; for, when the malady is advanced, local measures can, at the best, only be palliative, and are therefore subsidiary to judiciously devised means employed internally, and assisted by suitable diet and regimen.

28. Before I proceed to state the indications which should guide the treatment of this disease, and the medicines which seem best calculated to fulfil them, as far as this is possible, I will take a brief view of the means which have been recommended or tried by preceding writers. The real importance of this subject to the physician will be the more obvious, when he reflects, that cancerous diseases are often—indeed most legitimately on all occasions—within his province, more particularly when they invade, as they frequently do, internal organs; and that the life of the patient may be greatly prolonged, and his sufferings much alleviated, by judicious medical treatment.

29. A. At the commencement of the *scirrhous stage*, various means have been employed, and sometimes with some advantage, according to the showing of those who employed them. *Conium* has, upon the whole, found the greatest number of supporters; and I think that, when it has been combined with the alkaline tonic and stomachic preparations, it has been often of considerable benefit. This seems to be nearly the opinion of several writers, and amongst others, of GESNER (*Beobacht.* b. i. p. 213., iii. p. 242.), GIRARD, HUFELAND (*Journ. der Pract. Heilk.* b. ix. 3 st. p. 86.), HAHNEMANN (in *Ibid.* b. ii. p. 473.), and THILENIUS (*Med. und Chir. Bemerk.* p. 100.). ELECTRICITY and GALVANISM have been employed by BRISBANE (*Select Cases*, &c. p. 36.) and WALTHER (*Ueber die Ther. Ind. der Galv. Oper.* &c. c. 12.); the chloride of barium, by HUFELAND; antimonials, by ROWLEY and DOWNMAN; aconitum, by GREISING; digitalis, by MAYER (*Richter's Chirurg. Bibl.* b. v. p. 531.); laurel-water, by THILENIUS; mercury, particularly the bichloride, by RUYSCH, THILENIUS, and HARRIS; hydrochlorate of ammonia, by JUSTAMOND; belladonna, by GATAKER; and the mezereum, by HOME (*Clin. Exper. and Hist.* p. 428.), with more or less benefit, chiefly of a temporary kind in those cases which were obviously scirrhous, and with permanent service in those which were only supposed to be of this description.

30. B. In the more fully developed and less doubtful states of the disease, as well as in its earliest stage, a number of medicines have been recommended, and for a while have obtained some credit, which few of them have long retained. The great majority, however, of them have been

brought forward rather as palliatives, and with the view of keeping the disease in check, than as possessing the power of curing it; yet some have been exhibited with more sanguine expectations, particularly arsenic, conium, hyoscyamus, and belladonna.—*a.* That *conium* is productive of benefit, when judiciously combined with other remedies, is manifest, notwithstanding the contradictory evidence respecting it. While we find STÖERCK (*Lib. de Cicut. Vind.* 1761, 8vo.), FOTHERGILL (*Works*, vol. ii. p. 47.), HAMILTON, FRANCKE (*De Cancro. Ien.* 1778.), NICOLSON (*Med. Obs. and Enquir.* vol. iv. n. 31.), QUARIN (*De Cicuta*, ch. 4, 5.), FEARON, BELL (*On Ulcers*, pt. ii. sect. 8.), GRUELMANN (*De Usu Cicute*, &c. Goet. 1785.), RENARD (*Journ. de Med.* t. xxiii. p. 411.), SCHEFFER, and several other writers, in favour of it, we observe SIEBOLD (*Chir. Tageb.* n. 74.), LANGE, HILL (*Ed. Med. Comment.* vol. i. p. 146.), AKENSIDE (*Trans. of Col. of Phys.* vol. i. n. 6.), OBERTUEFFER (*Hufeland's Journ.* b. ix. st. 3. p. 81.), SCHNEIDER (*Chirurg. Gesch.* b. iv. n. 19.), and BURNS, expressing opinions as to either its little efficacy, or its entire want of effect. This discrepancy may be accounted for upon the supposition of want of virtue in the preparations prescribed; the extract generally losing the virtues of the plant during the modes of preparing it formerly in use: and I find, upon referring to most of the authors now quoted, and to others not referred to, that the extract and decoction were usually employed by those who found it productive of no benefit; whilst the powdered leaves, the expressed juice of the plant, or an infusion of it, had been preferred by those who have expressed themselves in favour of it. I have prescribed the inspissated juice and powdered leaves of this plant, in several cases of internal scirrhus-cancer, in combination with the alkalies and tonics, and have always found them much more beneficial when associated with it.

31. *b.* *Belladonna* was first exhibited by ALBERTI (*De Bellad. tanquam Specif. in Cancro*, &c. Halæ, 1739.), who highly praised it in the occult stage of the disease. It was afterwards recommended by LAMBERGEN (*Haller's Disp. Pract.* ii. n. 41.), BELLOT, LENTIN (*Beobacht. &c.* n. 2. and 3.), AMOUREUX (*Journ. de Méd.* t. xiii. p. 47.), CAMFERDON (*Ibid.* t. lv. p. 342. 423—502.), SULZER (*Ibid.* t. xxiv. p. 68.), and by GRANDVILLIERS (*Ibid.* t. xvi. p. 449.); and declared of little use by ZIMMERMANN and DE HAEN (*Rat. Med.* pt. ii. p. 37.). I believe, however, that some advantage will be procured from its internal and external use, particularly as a palliative, and when combined with medicines which are calculated to support the energies of life, and improve the secreting and digestive functions. A similar opinion may be offered respecting *stramonium* and *hyoscyamus*.

32. *c.* There is, perhaps, no medicine which has been so commonly prescribed in this malady as *arsenic*. It forms the base of the several secret remedies, internal as well as external, employed by empirics; and has been very generally used by them as an escharotic, sometimes with very injurious effects, from being absorbed largely into the system. There can be no doubt, however, of its beneficial influence, in many cases, when cautiously prescribed, and judiciously combined

with other medicines; but chiefly as a most energetic tonic and excitant of the capillary vessels, and powerful detergent in the ulcerative stage of the disease. JUSTAMOND prescribed it both internally and externally, with opium and various other medicines; STARK (*Archiv. f. d. Geburtsh.* b. ii. p. 673.), RUSH (*Edin. Med. Comment.* vol. xi. p. 312.), and OBELIUS, state that they have found it cure incipient cancer, when applied in solution to the part; COLLEBUSCH (in *Hufeland's Journ. d. Pract. Arn. &c.*, b. iii. p. 103.), found it beneficial when employed externally, tonic extracts having been given internally at the same time: FISCHER (in *Richter's Chir. Bibliog.* b. viii. p. 76.), MICHAELIS (in *Ibid.* b. v. p. 132.), and REUSSNER, prescribed it in the form of the powder of GUY* (composed of arsenic, sulphur, ranunculus sylvest., &c.), with marked benefit; SALMADE (*Mém. de la Soc. d'Emulat.* t. i. p. 152.) cured a case with the powder of Rousselot, the twenty-fifth part of which, he says, consists of arsenic; BALASCON DE TARARE gave it with the expressed juice of the solanum, and HORNUNG with serpentry and soot. This evidence, however, in its favour, is not without powerful opposition. FABRICIUS HILDANUS (*Cent.* vi. obs. 81.) says, that arsenic was introduced into practice by a monk named THEODORIC, in the tenth or eleventh century (having probably been made acquainted with it in the East), and details cases in which he considered it detrimental. A similar opinion has been entertained of it by SCHNEIDER, THILENIUS (*Med. und Chir. Bemerk.* p. 101.), ACREL, MURRAY (*Med. Pr. Bibl.* b. iii. p. 485.), ADAMS, OBERTUEFFER (*Stark's N. Archiv.* b. iv. p. 673.), and DELIUS. Mr. HILL, however, expresses a very favourable opinion as to the effects of this mineral, and states that it will retard the progress of the true scirrhus tumour, in the great majority of cases, and often prevent it from becoming cancer (*Ed. Med. and Surg. Journ.* vol. vi. p. 58.). I believe that, when this medicine is cautiously employed, both internally and externally, in conjunction with narcotics and alkalies, and with *iodine*, or otherwise judiciously combined, Mr. HILL's opinion in its favour is not much too highly coloured.

33. *d.* The preparations of *mercury* are always injurious in this disease, when exhibited in any other manner than as an alterative, and, externally, as an astringent and stimulating wash. The bichloride in minute doses internally, with the hydrochlorate of ammonia, or the compound sarsaparilla decoction, or with the tinctures of cinchona, guaiacum, &c., is often of service, at least in retarding the progress of its early stage; and when the disease has advanced to ulceration, the external use of the bichloride, with the hydrochlorate of ammonia, lime water, &c., may occasionally be of some service. REIDLIN (*Cur. Med. Millen.* n. 408.) states, that the preparations of this mineral are always injurious when productive of salivation. Of the accuracy of this opinion, there can be no doubt. Prescribed, however, as now recommended, it has received the approbation of MOSELEY, GOOCH, GMELIN (*Method. Cancrum Sanandi*, Tub. 1756.), HAGEN, GATAKER, CHAPUIS, BÜCHNER (*De Med. Mercur. Usu in Cancro*. Hal. 1755.),

* A secret remedy, recommended by RICHARD GUY, in a production, entitled *Essays on Scirrhus Tumours and Cancers*, 8vo. Lond. 1759.

CHAMPELLE (*Sur le Traitement du Cancer*. Par. an viii.), and by SIR A. COOPER (*Lectures*, in *Lancet*, vol. iii. p. 190.)

34. e. The preparations of iron have been recommended by JUSTAMOND and DE MARE (*Tract. Med. Chirurg. de Cancero*, 8c. Vien. 8vo. 1767.), who gave them variously combined, particularly with hydrochlorate of ammonia, and in the state of neutral salts. Mr. CARMICHAEL strenuously advises the sub phosphate, combined with a little pure fixed alkali. He prefers this preparation, but occasionally also employs the carbonate, the potas-io-tartrate of iron, the phosphate and oxyphosphate of the metal. If it occasion costiveness, he combines with it a little aloes; and if it produce headach, fever, or full pulse, he leaves it off, and gives four grains of camphor every five hours. He precribes it as follows; directing externally to ulcerated cancers, the carbonates, phosphates, or arseniate of iron, made into a thin paste with water; and to occult cancer a lotion constantly applied, consisting of a strong solution of some one of the salts of this metal.

No. 85. R Sub-Phosph. Ferri gr. xxx.—℞ij.; Potassee vcl. Sodae Purae gr. iij.—v.; Extr. Aloës gr. iv.; Puly. Glycyrrh. ℞j.; Albuminis Ovi q. s. ut fiat Pilulæ xij. Capiat binas, tertiis vel quartis horis.

Besides these preparations, the *ferris ammonio-chloridum* is entitled to notice. It was considered the best medicine that could be directed against this disease by Dr. DENMAN (*Observ. on the Cure of Cancer*, p. 77.).

35. f. The preparations of lead have also been used, chiefly externally, when the disease has advanced to ulceration. GESNER (*Beobach. b. v. p. 141.*) recommends the acetate in the form of liniment with turpentine, and SCHOENHEYDER (*Soc. Med. Hann. Coll. vol. i. n. 4.*), advises the continued application of lotions of this salt in a decoction of conium. It has also been used in thin sheets constantly pressed upon the scirrhus tumour. Of the various other remedies brought forwards by authors at different periods, and stated by them to have proved serviceable, I may briefly notice the following:—HORSTIUS (*Observ. l. ix. ob. 3.*) prescribed internally, and externally, sulphur, with spirit of turpentine; RULAND (*Cur. Ampir. i. n. 92.*), the balsamum sulphuris; and various other writers, the oleum sulphuris (F. 21.). The sulphurets have also been employed, both internally and externally, either alone, or with narcotics, and sometimes with benefit. GATAKER (*Observ. on the Intern. Use of the Solanum*. Lond. 1757.) used the *solanum nigrum*; and PAULUS ÆGINÆ (l. iv. c. 25.), ORIBASIVS (*Synop. l. vii. c. 13.*), and CARRER, the expressed juice of the *solanum dulcamara*, externally; the last-named author exhibiting it internally at the same time. Opium, as well as other narcotics, is often necessary in order to alleviate the patient's sufferings, and with this view has chiefly been employed. I believe, however, that, when combined with suitable remedies, it is otherwise productive of benefit. The volatile and fixed alkalies have been exhibited by BARKER (*New York Med. Repos. vol. iv. n. 4.*), MARTINET and BARBIATE (*Journ. de Méd. t. lvi. p. 559.*); antimoniats, by ROWLEY and TUEDEN (*Bemerk. b. ii. p. 38*); barytes by CRAWFORD (*Duncan's Med. Comment. vol. xiv. p. 433.*); cinchona, by HOMBURG, VIEUSSENS, and PLENK (*Samml. von Be-*

bucht. i. n. 6.); the expressed juice of the *chelandonium* and the sulphate of zinc, by BERCIELMANN; lime-water by VOGEL (*De Curat. Canciper Aquam Calcis Vivæ potam, 8c. Goet. 1769.*); the *orobanche virginiana*, by BARTON and BENSELL (*Philad. Med. Journ.*); an ointment with the juice of the *bardana* and acetate of lead, by PERCY (*Hufeland N. Annalen, i. p. 381.*); camphor, by several authors: the *sedum acre*, by BUCHOZ and QUESNAY; the *onopordum acanthium*, by GOETICKE (*De Onopordo Carcin. Aver. 8c. Fr. 1739.*), HANDEL, JUNCKER, and ROSS; myrrh, by NICOLAS (*Hufeland N. Annalen. i. p. 362.*); fixed airs, by BEDDOES, PERCIVAL, (*Essays, ii. p. 73.*), INGENIOUSZ, and PEYRIUÉ (*De Cancero, p. 75.*); digitalis, by RICHER (*Chirurg. Bibl. b. iv. p. 591.*); the hydro-sulphuret of ammonia, by BURNS; petroleum, by RAMMAZZINI and PIERCE; the *rhododendron chrysanthemum*, by PALLAS; and *aconitum, sarsaparilla, guaiacum, the beccabunga, the phellandrium aquaticum, 8c.* by various writers. All these have been prescribed both internally and externally, with little or no advantage, or with very temporary benefit only.

36. g. Of the numerous external remedies recommended at various periods, the preparations of arsenic and quicksilver; charcoal and carrot poultices; the mineral acids, particularly chlorine, hydro-chloric, and chloric acids; the chlorurets, and many of the metallic salts; camphor, the balsams, and the terebinthinate substances; ammoniacum, galbanum, and myrrh; and the greater part of the astringent, antiseptic, detergent, and stimulating vegetable medicines, have obtained a greater degree of reputation; and, when some of them are judiciously combined with one another, and with narcotics, they are deserving of notice as discutients in the early stage of the disease, and as palliatives in its ulcerating state.

37. Frictions of the part were advised by POUTEAU, and YOUNG entertained sanguine expectations of the result of pressure,—a practice which, very recently, has received the support of RECAMIER, and several French physicians. M. JOUBERT states, that he has found small local blood-lettings, and the following pills, most serviceable in the different stages of cancer. (*Archives Gén. vol. xvi. p. 282.*)

No. 86. R Saponis Medic. ʒiv.; Gum. Ammoniaci ʒij.; Ext. Conii et Ext. Aconiti Panic. ʒjss.; Massæ Pilul. Ruß ʒj. M. Contunde benè simul, et divide in Pilulas gr. v.

He directs two of these to be taken night and morning, increasing the dose by an additional one daily, until twelve, fifteen, or even twenty, are taken, morning and night. The rest of the treatment consists in applying poultices of the recent conium; using deobstruent and solvent beverages, a mild diet and regimen, and wearing an issue or seton in the arm or thigh. This plan has likewise been advised by Dr. LOWASSY, by whom it was first practised.

38. h. Sir A. COOPER expresses himself very strongly against low diet in this disease,—a practice which had been much insisted on by Mr. PEARSON, Dr. LANBE, and HUFELAND (*Journal der Pract. Arzneik. b. i. p. 289.*). The opinion of Sir ASTLEY is certainly in accordance with accurate observation, and rational induction. This very eminent surgeon states, that he has seen most benefit derived from PLUMMER'S pill given at bed-time,

and stomachic tonics in the day, consisting chiefly of the bitter infusions, with ammonia, and the carbonates of the alkalies. Some advantage was also derived from a pill, consisting of half a grain of stramonium, with two grains of camphor, given twice or thrice a day.

39. Since the introduction of *iodine* into practice, the preparations of it have been tried in the different stages of cancer by several physicians. The results of the trials which have been made of this substance are certainly such as ought to warrant the use of it in the early stages of the disease. The cases recorded by Dr. WAGNER (*Rev. Méd. Juin, 1823*), and by Mr. HILL, of Chester, are much in favour of it. I have been consulted in two cases occurring in females between thirty and forty, for what was considered, by the attending practitioners, *scirrhus mammae*, owing to the lancinating and remitting pains, and the diseased state of the nipple and axillary glands. They were both put upon a course of iodine (F. 328, 329.); with conium, and the solution of potash; a light nutritious diet, and strict attention to the state of the uterine functions, were also observed. Perfect recovery has taken place in both: but it appears doubtful whether or not they were genuine cases of scirrhus, notwithstanding the signs now alluded to were present. They had, however, withstood other means of cure for a long time. The treatment, in one of the cases, was chiefly conducted by Mr. FAXON, according to the above suggestions.

40. C. Conformably with the opinion stated above (§ 26.), I conceive that the treatment of this disease should be directed to the fulfilment of the following intentions:—1st, To support the energies of life, by exciting the digestive functions, and the abdominal secretions and excretions; 2d, To soothe the morbid sensibility of the part, and promote the absorption of morbid depositions in its tissues, by means of anodynes combined with deobstruents and discutients; and, 3d, To impart vigour to the frame by suitable medicine, diet, and regimen. The remedies which are calculated to fulfil the first indication, may be often conjoined with those intended to accomplish the second and third; and both internal and external means may be simultaneously used, with those views. The medicines already enumerated comprise nearly all that have been found of any service in this distressing malady. But the advantage to be derived from them will mainly depend upon their combination and exhibition appropriately to the circumstances of individual cases.

41. The preparations of *iodine* given in very small and frequently repeated doses, with iron—the iodide of iron—or with potash, and conium, or opium, will be found amongst the best remedies that can be used; inasmuch as, when exhibited in this manner, they are both tonic and deobstruent. They may also be used externally in the form of ointment; but one third of the proportion of iodide of potassium to the ointment usually employed should be prescribed, and friction with it ought to be of much longer continuance than commonly directed. Either stramonium, conium, opium, belladonna, hyoseyamus, or aconitum, may be given in various forms in the intervals between the exhibition of the iodine; and be combined with tonic infusions or decoctions, with the fixed or volatile alkalies, or with camphor in doses of

from two to six grains. They may also be tried in conjunction with the preparations of arsenic, or of iron, or the chlorates or potash, soda, or lime, and as external applications also, when the disease has gone on to ulceration. In females, scirrhus-cancer is generally connected, at its commencement, with disorder or the cessation of the menstrual discharge. In such cases, the preparations of iron with ammonia, or the fixed alkalies, and aloes, are sometimes of service. I have observed most advantage in these cases from frequent and full doses of conium, in the form of powder, given with the biborate of soda.

42. Tonic infusions, or decoctions, with liquor ammoniæ acetatis, or with the solution of potash, or the carbonates of the alkalies, and extract of conium, or the tincture of hyoseyamus; the bichloride of mercury in the compound tincture of cinchona, or compound decoction of sarsaparilla; or small doses of blue pill, or hydrarg. cum creta, with camphor, and either of the narcotic extracts; the preparations of sulphur and the sulphurets; the phosphates of iron, or this metal combined with ammonia, and conium; the sulphates of quinine and zinc; and the balsams and terebinthines; may severally be employed.

43. D. Although the malady obviously has a constitutional origin, yet the propriety of *extirpating the affected part*, as soon as the true scirrhus character becomes manifest, may be conceded. After this is accomplished, the constitutional vice may be more successfully combated, and the reappearance of the local disease more probably prevented than at a later period. When, however, the system exhibits any of the symptoms of the cancerous cachexia, whether the adjoining glands be enlarged or not, nothing will be gained by an operation; but some advantage may still accrue from judicious and energetic medical treatment, particularly from tonics combined with anodynes, alteratives, and deobstruents. Whilst

medical measures have often obtained the credit they by no means deserved, from the circumstance of local diseases mistaken for scirrhus having been removed by them; so I believe that surgical operations have sometimes acquired reputation from the same cause.

44. During the treatment of this malady attention must be especially directed to the secretions and evacuations. The bowels ought to be kept freely open with deobstruent laxatives, combined with tonics and vegetable bitters. The diet should be nutritious, and easy of digestion. Pork, in every state, ought to be avoided, as well as other indigestible kinds of meat. Change of air, and of scene, with agreeable amusements, serve essentially in assisting the influence of a judiciously devised method of cure, and should, therefore, not be overlooked by the practitioner; and several of the tonic and deobstruent mineral waters are of use, particularly those of Bath, Tunbridge, Buxton, Spa, Marienbad, &c.

CATALEPSY AND CATALEPTIC ECSTASY.

CLASSIF. 2. Class, Nervous Diseases; 1. Order, Comatose Affections (*Cullen*). 4. Class, Diseases of the Nervous Function; 4. Order, Affecting the Sensorial Powers (*Good*). II. CLASS, III. ORDER (Author, see Preface).

1. I. DESCRIPTION. — *Catalepsy and Ecstasy*, although treated of by some writers as distinct affections, generally present very nearly the same pathological conditions, as respects the presumed states of circulation in the brain, of vital energy, and of nervous influence; manifest similar morbid relations and complications, in their origin and progress; are so far modified in their symptoms as frequently to pass insensibly into each other; and therefore require, according to such manifestations, a treatment in all respects the same. For these reasons I shall consider them, in this article, as varieties of the same species of disease; and, if nothing more be gained by thus connecting them, repetition will be, at least, avoided.

i. CATALEPSY — TRANCE (from *καταληψις*, the action of seizing, and that from *καταλαμβάνω*, I seize). SYN. *Καταληψις*, Greek. *Catalepsia*, *Cataleptis*, *Catochas*, *Prehensio*, *Congelatio*, Auct. Lat. *Carus Ecstasis*, *Carus Catalepsia*, *Good*, *Antonia Cataleptis*, *Young*, *Catalepie*, Fr. *Die Sturrsucht*, *Kataleptis*, Ger. *Catalepie*, Ital. *Trance*.

2. DEFIN. — A sudden deprivation of sense, intelligence, and voluntary motion, the patient retaining the same position, during the paroxysm, in which he was at the moment of attack, or in which he may be placed during its continuance; the pulse and respiration being but little affected.

3. This disease is very rare; so much so, that its existence has been doubted by many writers, who consider it to have been feigned. Its occasional occurrence is, however, well ascertained. I have seen three cases of it in my own practice, and been consulted by letter respecting a fourth. I recollect, also, an undoubted example of it in an hospital, the practice of which I attended when a student. It presents no precise or undeviating train of symptoms, but varies in many particulars; the phenomena noticed in the definition being those most uniformly present. This varying character of the disease, according to the description given of it by authors, is owing to two circumstances; — 1st, to the modified state which it actually assumes, from the circumstances connected with its origin; and, 2dly, to certain of its phenomena having been more particularly noticed by some authors than by others, who have either mentioned them incidentally, or entirely overlooked them.

4. SYMPTOMS. — This is an intermittent and apyrexial disease, occurring in paroxysms of variable duration; and generally after very irregular intervals. The seizure is occasionally announced by premonitory symptoms, — by headach, mutability of temper, yawning, tinnitus aurium, vertigo, palpitations, lassitude, pain or slight spasm of the limbs or neck, confusion of mind, &c.; but it is commonly sudden, — the patient retaining the same expression of the countenance, and posture of the body, as at the moment of attack. The eyes are fixed, are open or shut, the pupils usually dilated, and imperfectly contractile from a strong light; and, from their unvarying expression, and the unchanged attitude, the body has the appearance of a statue. Any position, in which the head, trunk, or limbs are placed, is retained without deviation; the passive contractility of both the flexor and extensor muscles being such as to admit of a change as well as retention of the position during the paroxysm.

5. After a very indefinite duration — sometimes of only a few minutes, at others of several or even many hours, but rarely of days — the patient is restored to consciousness. In a remarkable case, however, detailed by Dr. Burrows, the fit lasted many days. Restoration is usually instantaneous, accompanied with sighing, shuddering, or rigidity of parts or the whole of the body, and followed by pain or confusion in the head, and a sense of fatigue and lassitude. The patient, it is said, has no recollection of what has passed during the fit: and the same ideas, and, according to some, even the same sentences, which had been suspended by the seizure, have been pursued, the moment of recovery. In the cases, however, that occurred in my practice, consciousness continued during the seizure.

6. The countenance, during the paroxysm, is sometimes little changed; at other times, it is paler than usual; but it is more commonly slightly suffused, and the pulsations of the carotids more forcible than natural. The respiration is variable, sometimes it is embarrassed; the temperature of the surface is also unequal; being generally depressed in the extremities, and increased in the head, evincing an irregular distribution of the circulation. The pulse is occasionally very slow; SAVAGES found it only 50; but it is more commonly quick and small. The senses are so entirely abolished, that the patient may be pinched without feeling it; and he cannot hear the loudest noises. The state of the muscles during the attack varies somewhat in different cases. They are often slightly rigid, but not to the extent of preventing the easy change of position of the limbs; and sometimes the position so permanently retained is one which no person in health could so long preserve. M. GEORGET states, that the muscles often present a degree of tetanic rigidity; but this is only sometimes the case, particularly when the disease is more nearly allied to *Ecstasy*. In some cases, it would seem as if a partial state of volition existed, of which the patient either had no consciousness, or a very imperfect consciousness at the time, and, consequently, no recollection of the act subsequently, as in some states of sleep.

7. In the more complete seizures, sense, intelligence, voluntary motion, and consciousness, are entirely abolished; but, in some instances, the abolition is only partial; the patient being conscious, but incapable of moving or speaking. This imperfect form of the disease has very generally received the appellation of *catochus* from nosologists; and numerous instances of it are on record. A very marked case, and nearly approaching to fully formed catalepsy, is recorded in the *Edinburg Medical Commentaries*, by Dr. FITZPATRICK; and slighter grades of it have been met with as a subordinate symptom of chronic nervous diseases, particularly of the severe and obstinate forms of hysteria. In a case, however, of well-marked *catochus*, in a female, detailed by Dr. LEBBECK, no hysterical symptoms existed; and, instead of unusual susceptibility of the system having been observed, in this and other cases which he had met with, more than common torpor was apparent. M. PETETIN and others, who believe in animal magnetism, conceive that sensation, instead of being lost for the time, is concentrated towards the epigastric region; and that the intelligence, so far from being altogether abolished, is exalted to a degree to amount almost to prophecy. But these opinions can only be applicable to ecstasy.

ii. CATALEPTIC ECSTASY. — *Ecstasis*, *Ecstasy* (from *εκστασις*, from *εξίστημι*). SYN. *Extase*, FR. *Entzückung*, *Begeisterung*, GER. *Estasi*, ITAL. *Ecstatic Trance*.

8. DEFIN. *Suspension of consciousness of external objects, and of voluntary motion, arising from, and attended by, a high degree of mental excitement and abstracted contemplation, the muscles continuing more or less rigidly contracted, or only partially relaxed.*

9. Under the term ecstasy, Dr. GOOD has described a variety of catalepsy, but little different from the usual appearance of that form of seizure, instead of the particular modification of disease to which the name ecstasy has usually

been applied. This variety of cataleptic disorder is generally induced by mental excitement and sustained contemplation of some particular subject, most generally of religious topics, and of those exciting the affections and passions. The patient suddenly seems mentally struck, or carried away from all external objects; either standing or sitting in a most excited and impassioned position, with the eyes fixed and open; and sometimes uttering either the most enthusiastic and fervid expressions, or the most earnest denunciations and warnings, or the most absurd exclamations, with the feeling or belief of their reality; and total abstraction from, or unconsciousness of, all surrounding objects or persons.

10. This affection is variously modified. In some cases it very nearly approaches to pure catalepsy; in others, to a sort of maniacal excitement. Dr. CHISHOLM records an instance of this latter state in a young female, in whom it alternated with mania; and I was consulted by a practitioner in the country respecting a most marked case occurring in a religious young lady, where it was evidently connected with, if not consisting of, an exalted form of hysteria. During the attack, she sung and composed long doggerel strains. Many of the cases which have lately made so much noise in this metropolis, under the idea of inspiration with "unknown tongues," evidently belong to this affection; at least, such of them as have not been feigned. The effects produced by the practisers of animal magnetism, upon nervous persons, sometimes appear allied to this affection. Many of the Italian improvisatori are possessed of this faculty only whilst they are in a state of ecstatic trance, similar to this disease. And few of them enjoy good health, or consider their faculty otherwise than a morbid one.
